A vanishing viscosity approach to a rate-independent damage model

Dorothee Knees ∗ Riccarda Rossi† Chiara Zanini‡

Abstract

We analyze a rate-independent model for damage evolution in elastic bodies. The central quantities are a stored energy functional and a dissipation functional, which is assumed to be positively homogeneous of degree one. Since the energy is not simultaneously (strictly) convex in the damage variable and the displacements, solutions may have jumps as a function of time. The latter circumstance makes it necessary to recur to suitable notions of weak solution. However, the by-now classical concept of global energetic solution fails to describe accurately the behavior of the system at jumps.

Hence, we consider rate-independent damage models as limits of systems driven by viscous, rate-dependent dissipation. We use a technique for taking the vanishing viscosity limit, which is based on arc-length reparameterization. In this way, in the limit we obtain a novel formulation for the rate-independent damage model, which highlights the interplay of viscous and rate-independent effects in the jump regime, and provides a better description of the energetic behavior of the system at jumps.

1 Introduction

In this paper, we focus on the modeling of damage in an elastic body $Ω ⊂ \mathbb{R}^d$, $d = 2, 3$, during a time interval $[0, T]$, as a rate-independent, activated process. The phenomenon is described in terms of a damage parameter $z : Ω × [0, T] → \mathbb{R}$, assessing the soundness of the material: usually, $z$ takes values in the interval $[0, 1]$, and one has $z(x, t) = 0$ ($z(x, t) = 1$, respectively), when the system at the process time $t \in [0, T]$ is fully damaged (completely sound), “locally” around $x \in Ω$. The driving energy is a function of time (through the external loading), of the damage parameter $z$, and of the displacement variable $u$. We consider small strains and assume that the elastic energy is quadratic. The external loading encompasses time-dependent displacement boundary conditions, as well as volume and surface loading. All in all, the stored energy functional $E : [0, T] × \mathcal{U} × \mathcal{Z} → \mathbb{R}$ (with the state space $\mathcal{U} = \left\{ v \in H^1(Ω, \mathbb{R}^d) ; v|_{Γ_D} = 0 \right\}$ for $u$, and $\mathcal{Z}$ the Sobolev-Slobodeckij space $H^s(Ω)$, $s \in \{1, \frac{3}{2}\}$, for $z$), is

$$E(t, u, z) := \frac{1}{2} a_s(z, z) + \int_{Ω} f(z) \, dx + \frac{1}{2} \int_{Ω} g(z) \mathcal{C} ε(u + u_D(t)) : ε(u + u_D(t)) \, dx - ⟨ℓ(t), u⟩_{\mathcal{U}}, \quad (1.1)$$

where $a_s$ is the bilinear form associated with the $H^s$ semi-norm on $\mathcal{Z} = H^s(Ω)$, $s \in \{1, \frac{3}{2}\}$, and $ε(u)$ is the symmetrized strain tensor. For the precise assumptions on the nonlinearities $f : \mathbb{R} → \mathbb{R}$ and $g : \mathbb{R} → \mathbb{R}$,

the elasticity tensor \( C \), the external loading \( \ell = \ell(t) \), and the Dirichlet datum \( u_D = u_D(t) \), we refer the reader to Section 2. We impose that at each time \( t \in [0,T] \) the displacement \( u(t) \) minimizes the energy \( E(t, \cdot, z(t)) \), namely
\[
u(t) \in \arg\min_{v \in \mathcal{U}} E(t, v, z(t)).
\]

Dissipation occurs through the internal, fast variable \( z \). As in [MR06, BMR09, TM10], we stay in the rate-independent framework, which characterizes phenomena where the external loading is much slower than the internal relaxation times. Hence, the evolution of \( z \) is described by the doubly nonlinear equation
\[
\partial \mathcal{R}_1(z'(t)) + D_z E(t, u(t), z(t)) \geq 0 \quad \text{in } \mathcal{Z}^* \quad \text{for a.a. } t \in (0, T).
\]

The above differential inclusion features the 1-positively homogeneous, unidirectional dissipation functional \( \mathcal{R}_1 : \mathcal{Z} \to [0, \infty] \) defined, for a given fracture toughness \( \kappa > 0 \) and \( \eta \in \mathcal{Z} \), by
\[
\mathcal{R}_1(\eta) = \begin{cases} \int_{\Omega} \kappa |\eta(x)| \, dx & \text{if } \eta \leq 0 \text{ a.e. in } \Omega, \\ \infty & \text{else.} \end{cases}
\]

In (1.2b), \( D_z E \) is the Gâteaux derivative of \( E \) w.r. to \( z \), whereas \( \partial \mathcal{R}_1 : \mathcal{Z} \rightrightarrows \mathcal{Z}^* \) is the (convex analysis) subdifferential of \( \mathcal{R}_1 \) in the frame of the duality between \( \mathcal{Z}^* \) and \( \mathcal{Z} \), i.e., for a given \( \eta \in \text{dom}(\mathcal{R}_1) \)
\[
\zeta \in \partial \mathcal{R}_1(\eta) \quad \text{if and only if} \quad \mathcal{R}_1(\eta) - \mathcal{R}_1(\zeta) \geq \langle \zeta, w - \eta \rangle_{\mathcal{Z}} \quad \text{for all } w \in \mathcal{Z}.
\]

We observe that the dissipation potential \( \mathcal{R}_1 \) only depends on \( z \), and this causes a lack of time compactness for \( u \), but introducing the reduced energy functional \( I \) allows us to deal with this degeneracy with respect to \( u \), and to formulate the problem only in the variable \( z \). With \( I : [0,T] \times \mathcal{Z} \to \mathbb{R} \), defined by \( I(t, z) = \inf_{v \in \mathcal{U}} E(t, v, z) \), equations (1.2a) and (1.2b) are combined into
\[
\partial \mathcal{R}_1(z'(t)) + D_z I(t, z(t)) \geq 0 \quad \text{in } \mathcal{Z}^* \quad \text{for a.a. } t \in (0, T).
\]

It will be shown in Lemma 2.7 that the Gâteaux derivative \( D_z I \) is well defined on \([0, T] \times \mathcal{Z}\) and, taking into account the concrete structure of \( D_z I \), (1.6) can be rewritten as
\[
\partial \mathcal{R}_1(z'(t)) + A_s z(t) + f'(z(t)) + \frac{1}{2} g'(z(t)) C e(u(t) + u_D(t)) : e(u(t) + u_D(t)) \geq 0 \quad \text{for a.a. } t \in (0, T),
\]

where \( A_s \) is the operator associated with the bilinear form \( a_s(\cdot, \cdot) \), and \( u \) fulfills (1.2a). The model studied here falls into the class of damage models introduced in [FN96, Kac86].

Notice that the range of \( \partial \mathcal{R}_1 \) is \( \partial \mathcal{R}_1(0) \), which, due to (1.3), is an unbounded subset of \( \mathcal{Z}^* \). This will cause difficulties when deriving uniform a-priori bounds. Since the reduced energy \( I \) arises as the minimum of a family of not necessarily convex functionals, one cannot rely on standard convexity arguments to study (1.6). Moreover, because of rate-independence we can only hope for a BV-control in time for \( z \), which does not prevent jumps. This calls for weak solvability notions for (1.6).

A well-established framework to describe rate-independent processes is the global energetic formulation developed by Mielke & Theil, see [MT99, MT04, Mie05], and used, in the context of damage modeling, in [MR06, BMR09, TM10, FKS12]. There, the evolution is characterized via a global stability criterion and an energy balance, which must be satisfied during the whole evolution. Due to the global stability condition, the prediction of the jumps of the solutions turns out to be not entirely satisfactory. Indeed,
global energetic solutions may change instantaneously in a very drastic way, jumping into very far-apart energetic configurations (see, for instance, [Mie03, Ex. 6.1], [KMZ08, Ex. 6.3], and [MRS09, Ex. 1]), while a local force balance criterion would predict a slow evolution.

In this paper, we discuss the vanishing viscosity approach as an alternative for the derivation of a local rate-independent damage model. The philosophy that rate-independence should be considered as limit of systems with smaller and smaller viscosity has by now been widely adopted in the applications, see, e.g., [TZ09, DDMM08, Cag08]. In the mainstream of the papers [EM06, MRS09, MRS12a, MZ12] on general rate-independent systems, [KMZ08, KZM10, LT11] for rate-independent models of crack propagation, and [BFM12, DDS11, DDS12] for rate-independent models in plasticity, we exploit this vanishing viscosity approach to obtain a more precise description of the system behavior at jumps. Hence, we approximate (1.6) with the doubly nonlinear equation

\[ \partial \mathcal{R}_\epsilon(z'(t)) + D_z \mathcal{I}(t, z(t)) \geq 0 \quad \text{in } Z^* \quad \text{for a.a. } t \in (0, T), \]  

where the dissipation functional \( \mathcal{R}_\epsilon \) features an additional \( L^2 \)-viscosity term, viz.

\[ \mathcal{R}_\epsilon(\eta) = \mathcal{R}_1(\eta) + \mathcal{R}_{2, \epsilon}(\eta) \quad \text{with } \mathcal{R}_{2, \epsilon}(\eta) = \frac{\epsilon}{2} \| \eta \|_{L^2(\Omega)}^2 + \epsilon \mathcal{R}_2(\eta) \quad \text{for } \eta \in Z. \]

Let us mention that damage models with viscous dissipation (possibly with viscosity and inertia in the displacement equation, and coupled with thermal effects) have been analyzed in [BS04, BSS05, BB08, FK06], as well as in [HK10], where damage is coupled with phase separation processes. Bridging a connection between the rate-dependent and rate-independent modeling approaches, in this paper we aim to study the limit of (1.8), as the viscosity parameter \( \epsilon \) tends to zero. Our vanishing viscosity results hinge on a preliminary analysis of the Cauchy problem for (1.8), for which we establish an existence result, cf. Theorem 3.3.

As it was shown in [EM06, MRS09, MRS12a, MZ12] for general rate-independent systems, passing to the limit as \( \epsilon \searrow 0 \) in (1.8) leads to an alternative weak formulation of (1.6), featuring a finer description of the solution jumps, which anyway occur later than for global energetic solutions. The key idea from [EM06] is that, at jumps the vanishing viscosity solutions to (1.6) follow a path which is reminiscent of the solution jumps, which anyway occur later than for global energetic solutions.

To reveal this, one has to go over to an extended state space and study the limiting behavior of the sequence \( (\hat{t}_\epsilon, \hat{z}_\epsilon) \), as \( \epsilon \downarrow 0 \), for a suitable reparameterization \( \hat{z}_\epsilon = z_\epsilon \circ \hat{t}_\epsilon \) of a family \( (z_\epsilon) \), of viscous solutions to (1.8), see (1.14) and (1.15) below. After establishing the relevant a-priori estimates in Section 4, in Section 5 we will prove that, up to a subsequence, the functions \( (\hat{t}_\epsilon, \hat{z}_\epsilon) \), converge to a so-called \( Z \)-parameterized solution of (1.6). While referring to Definition 5.2 for the precise assessment of \( Z \)-parameterized solutions, here we just mention that the limit pair \( (\hat{t}, \hat{z}) \) is a Lipschitz continuous curve \( (\hat{t}, \hat{z}) : [0, S] \to [0, T] \times Z \), fulfilling a parameterized doubly nonlinear evolution equation, viz.

\[ \partial \mathcal{R}_1(\hat{z}'(s)) + \lambda(s) \hat{z}'(s) + D_z \mathcal{I}(\hat{t}(s), \hat{z}(s)) \geq 0 \quad \text{in } Z^* \quad \text{for a.a. } s \in (0, S), \]

where \( \lambda : (0, S) \to (0, +\infty) \) is a Borel function such that \( \hat{\lambda}(s) \lambda(s) = 0 \) a.e. in \( (0, S) \). Notice that (1.10) encompasses both rate-independent evolution and, when the system jumps, the influence of rate-dependent dissipation. To reveal this, we observe that the time function \( \hat{t} : [0, S] \to [0, T] \) encodes the (slow) external time scale. When \( \hat{\lambda} > 0 \) on some interval \( (s_1, s_2) \), we have \( \lambda = 0 \) on \( (s_1, s_2) \), hence (1.10) is simply a parameterized version of (1.6): the system dissipation is only due to rate-independent, dry friction. When \( \hat{\lambda} = 0 \) on some interval \( (s_1, s_2) \), the external time is frozen. Indeed, the system has switched to a different regime, which is seen as a jump in the slow external time scale. If \( \lambda > 0 \) in (1.10), also viscous dissipation is active. This is in accordance with the following interpretation: jumps are fast
(with respect to the slow external time scale) transitions between two metastable states, during which the system may switch to a viscous regime. We refer to [EM06, MRS09, MRS12a], and to Section 5, for further observations on (1.10).

Let us shortly compare our model and results with the results for the damage model developed in [GL09, FG06]. In these papers, the influence of the damage state on the elastic properties is not postulated as in our case (where the effective tensor is defined by $g(z)C$), but it is the outcome of a certain homogenization procedure that takes place during the evolution process. It is shown in [GL09] that the solutions are (possibly discontinuous) threshold solutions. Roughly speaking, this means in particular that solutions do not jump before the forces reach a certain critical value. In the one-dimensional setting, the model from [GL09] can be reformulated in terms of a convex, but not strictly convex, reduced energy $\mathcal{I}$ (cf. Remark 6 in [FG06]) and the dissipation potential $\mathcal{R}_1$ from (1.3). In this one-dimensional case, due to the convexity of $\mathcal{I}$, the threshold solutions from [GL09] coincide with solutions of the corresponding global energetic model, as well as with the vanishing viscosity solutions considered here.

The main difficulties for the existence and vanishing viscosity analysis of (1.8) are of course related to its doubly nonlinear character. In particular, let us note in (1.7) the simultaneous presence of a quadratic term in $\varepsilon(u)$ (featured from the derivative $D_z\mathcal{I}$ of the nonconvex energy $\mathcal{I}$), and of the multivalued operator $\partial\mathcal{R}_1$. Indeed, differently from [EM06, MRS09, MRS12a, MZ12], here we are enforcing irreversibility, hence the operator $\partial\mathcal{R}_1 : Z \rightrightarrows Z^*$ is unbounded. This makes it difficult to derive suitable bounds for the thermodynamically conjugated force, i.e. the derivative $D_z\mathcal{I}$, and it motivates the presence of the regularizing term $\alpha_\varepsilon$ in the energy functional, hence our choice of the $Z$-topology, which is stronger than the natural one associated with $\mathcal{R}_1$. Indeed, one technical difficulty is that on the one hand it is possible to derive an estimate for $z'$ in $L^2(0,T;L^2(\Omega))$ and for the term $D_z\mathcal{I}(t,z(t))$ in the space $L^\infty(0,T;Z^*)$, and a comparison argument in (1.8) will not give additional information on $D_z\mathcal{I}$, due to the unboundedness of the term $\partial\mathcal{R}_1(z'(t))$. On the other hand, it is crucial both, for the existence and for the vanishing viscosity analysis of (1.8), that the terms $D_z\mathcal{I}$ and $z'$ are in duality.

In fact, the key step for the proof of existence of viscous solutions to (1.8) (cf. Theorem 3.3), is to obtain for viscous solutions $(z_\varepsilon)_{\varepsilon > 0} \subset H^1(0,T;L^2(\Omega))$, the improved bound

$$
\|z_\varepsilon'\|_{L^2(0,T;Z)} \leq C_\varepsilon,
$$

(1.11)

where $C_\varepsilon$ is a positive constant which depends on the viscosity parameter $\varepsilon$ and explodes as $\varepsilon \searrow 0$. We will prove (1.11) by means of careful estimates carried out for related time-discretization problems. Here we rely on a refined elliptic regularity result for the Euler-Lagrange equation for the minimum problem (1.2a), from the recent [HMW11]. We highlight that this regularity result does not hinge on smoothness of the boundary $\partial\Omega$, and thus it allows us to deal with a broad class of domains, as well as with mixed boundary conditions, which is crucial for real-world applications.

Next, we develop enhanced estimates, relying on the parabolic character of (1.7) and partially drawn from [MZ12]. In this way, we obtain for viscous solutions the further BV-bound

$$
\|z_\varepsilon'\|_{L^1(0,T;Z)} \leq C,
$$

(1.12)

for a constant $C$ which is now independent of $\varepsilon > 0$. Indeed, estimate (1.12) is the starting point for the vanishing viscosity analysis developed Theorem 5.3. Thanks to (1.12) it is possible to reparameterize viscous solutions $(z_\varepsilon)_{\varepsilon > 0}$ by the $Z$-arclength of their graph, which leads in the limit $\varepsilon \searrow 0$ to the aforementioned $Z$-parameterized solutions.

In Section 4 we shall prove the estimates (1.11) and (1.12) by working on the time-discretization scheme associated with (1.8): in particular, we shall suitably adapt to the time-discrete setting the arguments
from [MZ12, Lemma 3.4]. Note that this is not trivial and will involve an extension of the sharp, time-discrete Gronwall-type Lemma in [NSV00], cf. Lemma 4.9 later on. Moving from (1.12), we shall perform the vanishing viscosity analysis as $\epsilon \searrow 0$ in Section 5.

For a different approach to the proof of estimates (1.11) and (1.12) the reader is referred to the Preprint version of this article [KRZ11], where we regularize (1.8) by adding a $Z$-viscosity term, modulated by a “small” parameter $\delta > 0$. We obtain both estimate (1.11) (with a constant depending on $\epsilon$ but independent of $\delta$) and estimate (1.12) (with a constant independent of $\epsilon$ and $\delta$), for the solutions of the $\delta$-regularized viscous problem. Hence, we pass to the limit as $\delta \searrow 0$ and conclude the existence of solutions to the Cauchy problem for (1.8).

We emphasize that the time-discrete approach is clearly interesting in view of numerical analysis. Indeed, it has been proved in [MRS12a] (cf. also the forthcoming [MRS12c]) for general rate-independent systems, and in [KMZ08] for a crack propagation model that, passing to the limit in the time-discretization scheme for (1.8) as both the viscosity parameter $\nu$ and the time-step tend to zero, leads to the so-called BV solutions to (1.6). Loosely speaking, the latter concept is the “non-parameterized” version of the notion of parameterized solution. We plan to address within our damage model this simultaneous passage to the limit, as well as the analysis of BV solutions. Taking into account also spatial discretizations, the task is to derive relations between the discretization parameters (time-step size $\tau$, mesh size $h$, viscosity $\nu$) such that in the limit $(\tau_n, h_n, \nu_n) \to 0$ the approximate solutions converge to the vanishing viscosity solution (and not, for instance, to global energetic solutions), cf. [KS12], where a similar question for a crack propagation model is discussed. The arguments developed in Section 4 on the time-discrete problems will be fundamental for these studies.

A second issue we are going to address in the future, is to replace the linear $s$-Laplacian in (1.7) with the nonlinear $p$-Laplacian operator, which is usually found in models for damage, cf. [MR06, BMR09, TM10]. The key step for doing so will be to obtain, via regularity arguments, enhanced estimates for the term $D_zI(t,z(t))$ in (1.8). We are convinced that the careful study of the properties of the reduced functional $I$ performed in Section 2 as well as the discretization tools and estimates that have been established in Section 4, will be of some interest also in other contexts.

**Our main result.** For the reader’s convenience, we collect here the main results of this paper, referring to the statements throughout the paper for the precise assumptions.

First, in Section 2, relying on the recent regularity results from [HMW11] we derive basic properties of the marginal energy functional $I$. These include the Gâteaux-differentiability as well as continuity properties of $D_zI$ and $\partial_2I$ with respect to weak and strong convergence.

**Estimates (1.11) and (1.12)** are derived based on a time-discretization scheme associated with (1.8). We prove that for given $\epsilon > 0$, $z_0 \in Z$, and a partition $\{0 = t^0_0 < \ldots < t^N_N = T\}$ of the time interval $[0,T]$ with time step $\tau = t^j_{j+1} - t^j_{j}$, $k = 0, \ldots, N-1$, there exist elements $(\hat{z}^j_k)_{0 \leq k \leq N}$ such that $\hat{z}^j_0 = z_0$ and

$$
\partial R_1 \left( \frac{z^j_{k+1} - z^j_k}{\tau} \right) + \epsilon \frac{z^j_{k+1} - z^j_k}{\tau} + D_zI(t^j_{k+1},z^j_{k+1}) \ni 0. \quad (1.13)
$$

Hence we consider the piecewise linear interpolants $(\hat{z}_\tau)_\tau$ of the discrete solutions to (1.13) and, under suitable assumptions, in Theorem 4.3 show that for every sequence $\tau^j \searrow 0$ as $j \to \infty$ there exists a (not relabeled) subsequence of $(\hat{z}_\tau_j)$ and $z_\tau \in H^1(0,T;Z)$ such that $\hat{z}_\tau_j \rightharpoonup z_\tau$ weakly in $H^1(0,T;Z)$ and $z_\tau$ is a solution to the Cauchy problem for (1.8). Under additional regularity assumptions, in Theorem 3.7 we prove that the latter Cauchy problem in fact admits a unique solution $z_\tau \in H^1(0,T;Z)$. Further (cf. Proposition 4.5), in the case of dimension $d = 2$, if the initial datum $z_0$ fulfills $z_0(x) \in [0,1]$ for a.a. $x \in \Omega$,
then every viscous solution $z_\epsilon$ constructed via time-discretization also fulfills

$$z_\epsilon(t, x) \in [0, 1] \quad \text{for a.a. } x \in \Omega, \text{ for all } t \in [0, T].$$

The starting point for the vanishing viscosity analysis as $\epsilon \to 0$ is the crucial BV-estimate

$$\sup_{\epsilon > 0} \int_0^T \|z'_\epsilon(t)\|_Z \, dt \leq C_0$$

for viscous solutions to (1.8), see Theorem 3.3 and Corollary 4.8. Based on this, we are entitled to consider the graph $\text{Graph}(z_\epsilon) := \{(t, z_\epsilon(t)) ; t \in [0, T] \} \subset [0, T] \times Z$ and its $Z$-arclength parameterization

$$s_\epsilon(t) = t + \int_0^t \|z'_\epsilon(r)\|_Z \, dr. \quad (1.14)$$

For $S_\epsilon = s_\epsilon(T)$ we introduce the functions $\hat{t}_\epsilon : [0, S_\epsilon] \to [0, T]$ and $\hat{z}_\epsilon : [0, S_\epsilon] \to Z$

$$\hat{t}_\epsilon(s) := s_\epsilon^{-1}(s), \quad \hat{z}_\epsilon(s) := z_\epsilon(\hat{t}_\epsilon(s)) \quad (1.15)$$

and study the limiting behavior as $\epsilon \to 0$ of the parameterized viscous trajectories $\{(\hat{t}_\epsilon(s), \hat{z}_\epsilon(s)) ; s \in [0, S_\epsilon] \}$.  

In Theorem 5.3 and Proposition 5.7 we prove that there exist $S > 0$ such that for every sequence $\epsilon_n \searrow 0$, up to a not relabeled subsequence there exists a pair $(\hat{t}, \hat{z}) \in C^0_{\text{lip}}([0, S]; [0, T] \times Z)$ with

$$(\hat{t}_\epsilon, \hat{z}_\epsilon) \rightharpoonup (\hat{t}, \hat{z}) \quad \text{in } W^{1,\infty}(0, S; [0, T] \times Z),$$

and $(\hat{t}, \hat{z})$ is a $Z$-parameterized solution in the sense of Def. 5.2, fulfilling the parameterized doubly nonlinear evolution equation (1.10).

**Plan of the paper.** In Section 2 we set up the model and thoroughly analyze the properties of the reduced energy $I$. Next, in Section 3 we state Theorem 3.3 (=existence of solutions and a priori estimates uniform w.r. to the viscosity parameter $\epsilon$) for the Cauchy problem associated with (1.8). In Sec. 3 we also discuss uniqueness of viscous solutions under special assumptions. We prove Thm. 3.3 via a time-discretization in Section 4. Finally, in Section 5 we develop the vanishing viscosity analysis of (1.8).

## 2 The energy functional and its properties

### 2.1 Set-up

Hereafter $\Omega \subset \mathbb{R}^d$, $d \in \{2, 3\}$, is a bounded domain with Lipschitz boundary, and $\partial \Omega = \Gamma_D \cup \Gamma_N$, with the open Dirichlet boundary $\Gamma_D$ such that $\mathcal{H}^{d-1}(\Gamma_D) > 0$, and the Neumann boundary $\Gamma_N$. We shall assume that

$$\Gamma_D \text{ and } \Gamma_N \text{ are regular in the sense of Gröger, [Grö89],} \quad (2.1)$$

viz., loosely speaking, that the hypersurface separating $\Gamma_D$ and $\Gamma_N$ is Lipschitz.

**Notation.** For a given Banach space $X$, we shall denote by $\langle \cdot, \cdot \rangle_X$ the duality pairing between $X^*$ and $X$, and, if $X$ is a Hilbert space, we shall use the symbol $\langle \cdot, \cdot \rangle_X$ for its scalar product. For matrices $A, B \in \mathbb{R}^{m \times d}$ the inner product is defined by $A : B = \text{tr}(B^T A) = \sum_{i=1}^m \sum_{j=1}^d a_{ij} b_{ij}$.

The letter $Q$ shall stand for the space-time cylinder $\Omega \times (0, T)$. The following function spaces and notation shall be used for $\sigma \geq 0, p \in [1, \infty]$:

6
Furthermore, since notice that let $g$ hereafter, we shall suppose for the elasticity tensor that we have $A$ by $s < 2$, so that the associated bilinear form on $Z$ is:

\begin{align}
  a_s(z_1, z_2) &= \int_{\Omega} \nabla z_1 \cdot \nabla z_2 \, dx \quad \text{if } s = 1, \\
  a_s(z_1, z_2) &= \int_{\Omega} \int_{\Omega} \frac{(\nabla z_1(x) - \nabla z_1(y)) \cdot (\nabla z_2(x) - \nabla z_2(y))}{|x - y|^{2(s-1)}} \, dx \, dy \quad \text{if } s \in (1, 2). 
\end{align}

Recall that $Z$ is a Hilbert space, with the inner product $(z_1, z_2)_Z = (z_1, z_2)_{L^2(\Omega)} + a_s(z_1, z_2)$. We denote by $A_s : Z \to Z^*$ the associated operator, viz.

\begin{equation}
  (A_s(z), w)_Z := a_s(z, w) \quad \text{for every } z, w \in Z.
\end{equation}

Notice that

\begin{equation}
  Z \subseteq L^r(\Omega) \quad \text{for every } r \in [1, \infty).
\end{equation}

Furthermore, since $Z$ is dense in $L^2(\Omega)$, we have that $(Z, L^2(\Omega) \cong L^2(\Omega)^*, Z^*)$ is a Hilbert triple. In particular, every element of $L^2(\Omega)$ is identified with an element in $Z^*$, and we thus have

\begin{equation}
  Z \subseteq L^2(\Omega) \subseteq Z^*.
\end{equation}

### 2.2 The energy functional

The energy is given by the sum of the elastic energy and an energy only depending on the damage variable. As for the latter contribution, we consider a function

\begin{equation}
  f \in C^2(\mathbb{R}), \quad \text{such that } \exists K_1, K_2, K_3 > 0 \quad \forall x \in \mathbb{R} : \quad |f''(x)| \leq K_1 \quad \text{and } f(x) \geq K_2 |x|^2 - K_3.
\end{equation}

A typical choice for $f$ is $f(z) = (1 - z)^2$, see [Gia05]. We then have the functional

\begin{equation}
  \mathcal{I}_1 : Z \to \mathbb{R} \quad \text{defined by } \mathcal{I}_1(z) := \frac{1}{2} a_s(z, z) + \int_{\Omega} f(z) \, dx.
\end{equation}

Linearly elastic materials are considered with an elastic energy density

\begin{equation}
  W(x, \eta) = \frac{1}{2} C(x) \eta : \eta, \quad \text{for } \eta \in \mathbb{R}^{d \times d}_{\text{sym}} \text{ and almost every } x \in \Omega.
\end{equation}

Hereafter, we shall suppose for the elasticity tensor that

\begin{equation}
  C \in L^\infty(\Omega, \text{Lin}(\mathbb{R}^{d \times d}_{\text{sym}}, \mathbb{R}^{d \times d}_{\text{sym}}))
\end{equation}

\begin{equation}
  \exists \gamma_0 > 0 \quad \text{for all } \xi \in \mathbb{R}^{d \times d}_{\text{sym}} \text{ and almost all } x \in \Omega : \quad C(x) \xi : \xi \geq \gamma_0 |\xi|^2.
\end{equation}

Let $g : \mathbb{R} \to \mathbb{R}$ be a further constitutive function such that

\begin{equation}
  g \in C^2(\mathbb{R}), \quad \text{with } g', g'' \in L^\infty(\mathbb{R}), \quad \text{and } \exists \gamma_1, \gamma_2 > 0 : \quad \forall z \in \mathbb{R} : \quad \gamma_1 \leq g(z) \leq \gamma_2.
\end{equation}
Given an external loading \( \ell \in C^0([0, T], U^*) \) and a Dirichlet datum \( u_D \in C^0([0, T]; H^1(\Omega, \mathbb{R}^d)) \), we take the elastic energy

\[
\mathcal{E}_2 : [0, T] \times U \times Z \to \mathbb{R} \text{ defined by } \mathcal{E}_2(t, u, z) := \int_\Omega g(z)W(\varepsilon(u + u_D(t))) \, dx - \langle \ell(t), u \rangle_U
\]

where \( \varepsilon(u) = \frac{1}{2}(\nabla u + \nabla u^T) \) is the symmetrized strain tensor. For \( u \in U \) and \( z \in Z \) the stored energy is then defined as

\[
\mathcal{E}(t, u, z) = \mathcal{I}_1(z) + \mathcal{E}_2(t, u, z).
\]

Minimizing the stored energy with respect to the displacements we obtain the reduced energy

\[
\mathcal{I} : [0, T] \times Z \to \mathbb{R} \text{ given by } \mathcal{I}(t, z) = \mathcal{I}_1(z) + \mathcal{I}_2(t, z) + \inf \{ \mathcal{E}_2(t, v, z) ; v \in U \}. \tag{2.12}
\]

Remark 2.1. For our main results on the vanishing viscosity analysis of (1.6) (cf. Theorems 3.3 and 5.3 later on), it will be sufficient to suppose that the index \( s \) in (2.3) fulfills \( s = \frac{d}{2} \). In particular, let us highlight that, in the bi-dimensional case \( d = 2 \), we have \( s = 1 \), hence the operator \( A_s \) reduces to the usual Laplacian operator.

Remark 2.2. As we have already pointed out, the irreversibility of the damage process is enforced in our model through the choice of the dissipation functional (1.3). Instead, so far we have not included in our model the constraint that the damage variable \( z \) only take values in \([0, 1]\): indeed, the term \( I_{[0,1]}(z) \) does not contribute to the energy \( \mathcal{I} \). However, in Section 4 we shall prove via a time-discretization procedure that, in the bi-dimensional case \( d = 2 \) and under suitable assumptions on the nonlinearities \( g \) and \( f \), if the initial datum \( z_0 \) satisfies \( z_0(x) \in [0, 1] \) for almost every \( x \in \Omega \), then there exists a viscous solution \( z \in H^1(0, T; Z) \) with \( z(0) = z_0 \) and \( z(x) \in [0, 1] \) for almost every \( x \in \Omega \). Ultimately, with the vanishing viscosity analysis developed in Section 5, we shall obtain parameterized solutions to the rate-independent system for damage, which only take values in \([0, 1]\). The proof relies on a comparison principle argument that cannot be adapted to the case with \( H^s \)-regularizations, \( s \geq \frac{3}{2} \). However, using a \( p \)-Laplace-like regularization instead of a \( H^s \)-regularization would allow us to prove the non-negativity of \( z \) also in higher space dimension.

Notation 2.3. Hereafter, throughout the paper we shall use the symbols \( c, c', C, C' \) for various positive constants which only depend on known quantities, and whose meaning may vary even in the same line.

2.3 Properties of the energy functional

A regularity result from [HMW11]. The following result has been recently proved in [HMW11] (cf. Thm. 1.1 therein): For \( C \) as in (2.9a), \( g \) as in (2.10), and \( z \in Z \), let \( L_z \) be the linear elliptic operator defined by

\[
\langle L_z(v), w \rangle_U := \int_\Omega g(z(x))C(x)\varepsilon(v(x)) : \varepsilon(w(x)) \, dx \text{ for all } v, w \in U. \tag{2.13}
\]

Then,

there exists \( p > 2 \) s.t. for all \( \tilde{p} \in [2, p] \)

\[
L_z : W^{1,\tilde{p}}_{\Gamma_D}(\Omega; \mathbb{R}^d) \to W^{-1,\tilde{p}}_{\Gamma_D}(\Omega; \mathbb{R}^d) \text{ is an isomorphism,} \tag{2.14}
\]

and there exists some constant \( c_0 > 0 \), only depending on \( \|C\|_{L^\infty(\Omega)} \) and \( \|g\|_{L^\infty(\mathbb{R})} \), such that

\[
\|L_z^{-1}h\|_{W^{1,\tilde{p}}_{\Gamma_D}(\Omega)} \leq c_0\|h\|_{W^{-1,\tilde{p}}_{\Gamma_D}(\Omega)} \text{ for all } h \in W^{-1,\tilde{p}}_{\Gamma_D}(\Omega) \text{ and } \tilde{p} \in [2, p]. \tag{2.15}
\]
Notice that, in particular, the integrability exponent \( p \) and the constant \( c_0 \) are independent of \( z \in \mathcal{Z} \). Relying on this regularity result, in the next lemmatas we prove some crucial properties of the reduced energy (2.12).

**Assumptions on the initial data.** Hereafter, we shall require that

\[
\ell \in C^{1,1}([0, T]; W^{-1,p}_D(\Omega; \mathbb{R}^d)), \quad u_D \in C^{1,1}([0, T]; W^{1,p}(\Omega; \mathbb{R}^d)) \quad \text{with} \quad p > 2 \quad \text{from} \quad (2.14).
\]

(2.16)

**Coercivity of the reduced energy and properties of minimizers.**

**Lemma 2.4** (Existence of minimizers and their regularity).

Let \( s = d/2 \). Under assumptions (2.1), (2.8)–(2.10), and (2.16), for every \((t, z) \in [0, T] \times \mathcal{Z}\) there exists a unique \( u_{\min}(t, z) \in \mathcal{U} \), which minimizes \( \mathcal{E}(t, z, \cdot) \). Moreover, there exists \( p > 2 \) such that for all \( \tilde{p} \in [2, p] \) and \((t, z) \in [0, T] \times \mathcal{Z}\) it holds that \( u_{\min}(t, z) \in W^{1,\tilde{p}}_D(\Omega) \), and

\[
\forall (t, z) \in [0, T] \times \mathcal{Z}: \| u_{\min}(t, z) \|_{W^{1,\tilde{p}}_D(\Omega)} \leq c_0 \left( \| \ell(t) \|_{W^{-1,\tilde{p}}_D(\Omega)} + \| u_D(t) \|_{W^{1,\tilde{p}}_D(\Omega)} \right),
\]

(2.17)

where \( c_0 \) is the constant from (2.15). Furthermore, the following coercivity inequality for \( \mathcal{I} \) is valid: There exist constants \( c_1, c_2 > 0 \) such that for all \((t, z) \in [0, T] \times \mathcal{Z}\) it holds

\[
\mathcal{I}(t, z) \geq c_1 \left( \| z \|_{H^{s}(\Omega)}^2 + \| u_{\min}(t, z) \|_{H^{s}(\Omega)}^2 \right) - c_2.
\]

(2.18)

**Proof.** Taking into account (2.10), (2.16), and employing Korn’s inequality, it is immediate to see that for every \((t, z) \in [0, T] \times \mathcal{Z}\) the functional \( \mathcal{E}_2(t, z, \cdot) \) is uniformly convex on \( \mathcal{U} \). Therefore, \( \mathcal{E}_2(t, z, \cdot) \) (and, hence, \( \mathcal{E}(t, z, \cdot) \)) has a unique minimizer \( u_{\min}(t, z) \), satisfying the Euler equation

\[
L_z u_{\min}(t, z) + u_D(t) = \ell(t) \quad \text{for every} \quad t \in [0, T].
\]

(2.19)

Since \( \ell(t) \in W^{-1,p}_D(\Omega) \) for all \( t \in [0, T] \) by (2.16), from (2.14) we deduce that \( u_{\min}(t, z) \in W^{1,\tilde{p}}_D(\Omega) \) for all \( \tilde{p} \in [2, p] \). Then, (2.17) follows from (2.15) and assumption (2.16).

Finally, estimate (2.18) follows from combining

\[
\mathcal{I}_2(t, z) = \mathcal{E}_2(t, u_{\min}(t, z), z) \geq \frac{\gamma_1}{2} \int_{\Omega} |z(u_{\min}(t, z) + u_D(t))|^2 dx - \| \ell(t) \|_{H^{-1}(\Omega)} \| u_{\min}(t, z) \|_{\mathcal{U}} \geq C \| u_{\min}(t, z) \|^2_{\mathcal{U}} - C' \left( \| u_D \|^2_{L^\infty(0,T; H^s(\Omega))} + \| \ell \|^2_{L^\infty(0,T; H^{-1}(\Omega))} \right),
\]

(2.20)

where we have again used (2.10), Korn’s inequality, (2.16) and (2.17)), with

\[
\mathcal{I}_1(t, z) \geq \frac{1}{2} \beta s \| z \|^2_{L^2(\Omega)} - C' \geq C \| z \|^2_{H^s(\Omega)} - C',
\]

where the first inequality follows from (2.8), and the second one from a Poincaré-type inequality. \( \square \)

**Lemma 2.5** (Continuous dependence on the data).

Let \( s = d/2 \). Under assumptions (2.1), (2.8)–(2.10), there exists a constant \( c_3 > 0 \) such that for all \( \ell \) and \( u_D \) with (2.16), all \( z_1, z_2 \in \mathcal{Z} \), all \( t_1, t_2 \in [0, T] \) and all \( \tilde{p} \in [2, p] \) it holds with \( r = p\tilde{p}(p - \tilde{p})^{-1} \)

\[
\| u_{\min}(t_1, z_1) - u_{\min}(t_2, z_2) \|_{W^{1,\tilde{p}}(\Omega)} \leq c_3 \left( \| t_1 - t_2 \| + \| z_1 - z_2 \|_{L^r(\Omega)} \right) \left( \| \ell \|_{C^{1}([0,T]; W^{-1,\tilde{p}}_D(\Omega))} + \| u_D \|_{C^{1}([0,T]; W^{1,p}(\Omega))} \right).
\]

(2.20)
Proof. For \( i = 1, 2 \), let \( u_i := u_{\min}(t_i, z_i) \in W^{1,p}(\Omega) \), with \( p \) from Lemma 2.4. From the Euler-Lagrange equation (2.19) written for \( u_i \), \( i = 1, 2 \), with algebraic manipulations we obtain that \( u_1 - u_2 \) satisfies for all \( v \in \mathcal{U} \)

\[
\int_{\Omega} g(z_1)\varepsilon(u_1 - u_2) : \varepsilon(v) \, dx = \int_{\Omega} (g(z_2) - g(z_1))\varepsilon(u_2) : \varepsilon(v) \, dx \\
- \int_{\Omega} (g(z_1)\varepsilon(u_D(t_1)) - g(z_2)\varepsilon(u_D(t_2))) : \varepsilon(v) \, dx + \langle \ell(t_1) - \ell(t_2), v \rangle_{\mathcal{U}}.
\]

(2.21)

Hence, the function \( u_1 - u_2 \) fulfills

\[
\int_{\Omega} g(z_1)\varepsilon(u_1 - u_2) : \varepsilon(v) \, dx = \langle \hat{\ell}_{1,2}, v \rangle \quad \text{for all} \; v \in \mathcal{U},
\]

where \( \hat{\ell}_{1,2} \in W^{-1,p}(\Omega) \) subsumes the terms on the right-hand side of (2.21). Therefore, (2.15) gives

\[
\|u_1 - u_2\|_{W^{1,p}(\Omega)} \leq c_0 \left\| \hat{\ell}_{1,2} \right\|_{W^{-1,p}(\Omega)},
\]

whence we deduce the estimate

\[
\|u_1 - u_2\|_{W^{1,p}(\Omega)} \leq c_0 \left( \|\ell(t_1) - \ell(t_2)\|_{W^{-1,p}(\Omega)} + \left\| (g(z_1) - g(z_2))\varepsilon(u_2) \right\|_{L^p(\Omega)} \\
+ \left\| (g(z_1)\varepsilon(u_D(t_1)) - g(z_2)\varepsilon(u_D(t_2))) \right\|_{L^p(\Omega)}. \quad (2.22)
\]

Now, the Lipschitz continuity of \( g \) and Hölder’s inequality imply that

\[
\|g(z_1) - g(z_2)\varepsilon(u_2)\|_{L^p(\Omega)} \leq C \|z_1 - z_2\|_{L^p(\Omega)} \|\varepsilon(u_2)\|_{L^p(\Omega)} \leq C' \|z_1 - z_2\|_{L^p(\Omega)} \quad (2.23)
\]

with \( r = \tilde{p}\tilde{p}(p - \tilde{p})^{-1} \), where the second inequality follows from (2.16) and from estimate (2.17). We use (2.23) to estimate the second term on the right-hand side of (2.22). As for the third summand, we have

\[
\|g(z_1)\varepsilon(u_D(t_1)) - g(z_2)\varepsilon(u_D(t_2))\|_{L^p(\Omega)} \\
\leq \left\| (g(z_1) - g(z_2))\varepsilon(u_D(t_1)) \right\|_{L^p(\Omega)} + \left\| g(z_2)\varepsilon(u_D(t_1)) - \varepsilon(u_D(t_2)) \right\|_{L^p(\Omega)} \\
\leq C \left( \|z_1 - z_2\|_{L^p(\Omega)} \|u_D\|_{L^\infty(\Omega)} + \|u_D(t_1) - u_D(t_2)\|_{W^{1,p}(\Omega)} \right), \quad (2.24)
\]

where the latter inequality again follows from (2.23), and from the fact that \( g \in L^\infty(\mathbb{R}) \). Combining all of the above inequalities, and relying on (2.16), we finally arrive at (2.20). \( \blacksquare \)

Differentiability w.r. to time.

Lemma 2.6 (Differentiability and growth w.r. to time).

Let \( s = d/2 \). Under assumptions (2.1), (2.8)-(2.10) and (2.16), for every \( z \in \mathcal{Z} \) the map \( t \mapsto I(t,z) \) belongs to \( C^1([0,T], \mathbb{R}) \) with

\[
\partial_t I(t,z) = \int_{\Omega} g(z)\varepsilon(u_{\min}(t,z) + u_D(t)) : \varepsilon(u_D(t)) \, dx - \langle \ell(t), u_{\min}(t,z) \rangle. \quad (2.25)
\]

Moreover, there exists a constant \( c_4 > 0 \) such that for all \( t \in [0,T], z \in \mathcal{Z} \) and \( u_D \), \( \ell \) with (2.16) we have

\[
|\partial_t I(t,z)| \leq c_4 \left( \|u_D\|_{C^1([0,T],W^{1,p}(\Omega))}^2 + \|\ell\|_{C^1([0,T],W^{-1,p}(\Omega))}^2 \right). \quad (2.26)
\]

Finally, for all \( r \in [\frac{p}{p-2}, \infty) \) there exists a constant \( c_5 > 0 \) depending on \( \|\ell\|_{C^1([0,T],W^{-1,p}(\Omega))} \) and \( \|u_D\|_{C^1([0,T],W^{1,p}(\Omega))} \) such that for all \( t_i \in [0,T] \) and \( z_i \in \mathcal{Z} \) we have

\[
|\partial_t I(t_1,z_1) - \partial_t I(t_2,z_2)| \leq c_5 \left( |t_1 - t_2| + \|z_1 - z_2\|_{L^p(\Omega)} \right). \quad (2.27)
\]
Proof. Relation (2.25) follows from direct calculations. Then,

\[
|\partial_t \mathcal{I}(t, z)| \leq c_3 \|u_D\|_{C^1([0,T]; H^1(\Omega))} + \|\varepsilon\|_{C^1([0,T]; \mathcal{M}')} \|u_{\min}(t, z)\|_{H^1(\Omega)} + c_5 \|u_D\|_{C^2([0,T]; H^1(\Omega))}^2.
\]

In view of (2.17) we arrive at (2.26). In order to prove (2.27), we calculate

\[
\begin{align*}
\partial_{t} \mathcal{I}(t_1, z_1) - \partial_{t} \mathcal{I}(t_2, z_2)
&= \int_{\Omega} (g(z_1) - g(z_2)) C(\varepsilon(u_{\min}(t_1, z_1) + u_D(t_1))) : \varepsilon(\ddot{u}_D(t_1)) \, dx \\
&+ \int_{\Omega} g(z_2) C(\varepsilon(u_{\min}(t_1, z_1) + u_D(t_1)) - \varepsilon(u_{\min}(t_2, z_2) + u_D(t_2))) : \varepsilon(\ddot{u}_D(t_1)) \, dx \\
&+ \int_{\Omega} \dot{g}(z_2) C(\varepsilon(u_{\min}(t_2, z_2) + u_D(t_2))) : (\varepsilon(\ddot{u}_D(t_1)) - \varepsilon(\ddot{u}_D(t_2))) \, dx \\
&- \langle \tilde{\ell}(t_1) - \tilde{\ell}(t_2), u_{\min}(t_1, z_1) \rangle + \langle \tilde{\ell}(t_2), u_{\min}(t_2, z_2) - u_{\min}(t_1, z_1) \rangle = I_1 + I_2 + I_3 + I_4 + I_5.
\end{align*}
\]

To estimate $I_1, I_2,$ and $I_3$ we rely on the fact that $g, g' \in L^\infty(\mathbb{R})$, on the previously proved (2.17) and (2.20), and on the following Hölder-estimate: For $z \in Z$ and $v_1, v_2 \in W^{1, q}(\Omega)$ we have

\[
\|z \nabla v_1 \nabla v_2\|_{L^r(\Omega)} \leq \|z\|_{L^r(\Omega)} \|v_1\|_{W^{1, s}(\Omega)} \|v_2\|_{W^{1, s}(\Omega)},
\]

with $q$ defined by $\frac{1}{q} + \frac{2}{3} = 1$, i.e. $r = q/(q-2)$. The estimates for $I_4$ and $I_5$ ensue from (2.16) and (2.20). \(\Box\)

Differentiability w.r.t $z$. The differentiability of $\mathcal{I}$ with respect to $z$ will be studied in the $Z - Z^*$ duality. In particular, $D_z \mathcal{I}(t, \cdot) : Z \rightarrow Z^*$ shall denote the Gâteaux-differential of the functional $\mathcal{I}(t, \cdot)$.

Lemma 2.7 (Gâteaux-differentiability).

Let $s = d/2$. Under assumptions (2.1), (2.8)–(2.10) and (2.16), for all $t \in [0, T]$ the functional $\mathcal{I}(t, \cdot) : Z \rightarrow \mathbb{R}$ is Gâteaux-differentiable at all $z \in Z$, and for all $\eta \in Z$ we have

\[
D_z \mathcal{I}(t, z)[\eta] = a_{z}(z, \eta) + \int_{\Omega} f'(z) \eta \, dx + \int_{\Omega} g'(z) \tilde{W}(t, \nabla u_{\min}(t, z)) \eta \, dx,
\]

where we use the abbreviation $\tilde{W}(t, \nabla v) = W(\nabla v + \nabla u_D(t)) = \frac{1}{2} C(\varepsilon(v + u_D(t))) z(v + u_D(t))$. In particular, the following estimate holds

\[
\exists c_6 > 0 \ \forall (t, z) \in [0, T] \times Z : \|D_z \mathcal{I}(t, z)\|_{Z^*} \leq c_6 \|z\|_{Z + 1}.
\]

Proof. The Gâteaux-differentiability of $\mathcal{I}_1$ follows from the definition of the bilinear form $a_{z}(\cdot, \cdot)$ and assumption (2.8) on $f$. We only have to verify the Gâteaux-differentiability of $\mathcal{I}_2(t, z)$. In this direction, let $u \in W^{1, \tilde{p}}(\Omega)$ with $\tilde{p} \in (2, p)$, $p$ as in Lemma 2.4, and $t \in [0, T]$ be fixed. The mapping $E_2(t, u, \cdot) : Z \rightarrow \mathbb{R}$ is Gâteaux-differentiable, as shown by the following calculations: Let $z, \eta \in Z$, $h \in \mathbb{R} \backslash \{0\}$, and set

\[
b_h(z, \eta) := h^{-1} (E_2(t, u, z + h\eta) - E_2(t, u, z)) = \int_{0}^{1} g'\left(z + \sigma h\eta\right) \tilde{W}(t, \nabla u) d\sigma.
\]

For $h \rightarrow 0$ the integrand pointwise converges to $g'(z) \eta \tilde{W}(t, \nabla u)$. Moreover, since $Z \subset L^r(\Omega)$ for all $r \in [1, \infty)$ and since $\tilde{W}(t, \nabla u) \in L^{\tilde{p}}(\Omega)$, the function $x \mapsto ||g'||_{L^\infty(\mathbb{R})} |\eta(x)| \tilde{W}(t, \nabla u(x))$ is an integrable majorant. Hence, with Lebesgue’s theorem it follows that for $h \rightarrow 0$ the sequence $(b_h(z, \eta))_h$ converges to $b(z, \eta) := \int_{\Omega} g'(z) \eta \tilde{W}(t, \nabla u) \, dx$. Observe that for every $z$ the mapping $b(z, \cdot) : Z \rightarrow \mathbb{R}$ is an element of $Z^*$. This proves that $E_2(t, u, \cdot)$ is Gâteaux differentiable, with

\[
D_z E_2(t, u, z)[\eta] = \int_{\Omega} g'(z) \eta \tilde{W}(t, \nabla u) \, dx \quad \text{for all } \eta \in Z.
\]
The previous calculations show that for $h \searrow 0$ we have
\[
\lim_{h \searrow 0} h^{-1}(\mathcal{I}_2(t, z + h\eta) - \mathcal{I}_2(t, z)) \leq \lim_{h \searrow 0} h^{-1}(\mathcal{E}_2(t, u_{\min}(t, z), z + h\eta) - \mathcal{E}_2(t, u_{\min}(t, z), z)) = D_z\mathcal{E}_2(t, u_{\min}(t, z), z)[\eta].
\]

On the other hand, for $h > 0$ the following inequality is valid:
\[
h^{-1}(\mathcal{I}_2(t, z + h\eta) - \mathcal{I}_2(t, z)) \geq h^{-1}(\mathcal{E}_2(t, u_{\min}(t, z + h\eta), z + h\eta) - \mathcal{E}_2(t, u_{\min}(t, z + h\eta), z)) = \int_{\Omega} \int_{0}^{1} g'(z + \sigma h\eta)\eta \widetilde{W}(t, \nabla u_{\min}(t, z + h\eta)) d\sigma dx.
\]

Choose $2 < \tilde{p} < p$ with $p$ from Lemma 2.4. From (2.20) it follows that $u_{\min}(t, z + h\sigma\eta) \to u_{\min}(t, z)$ strongly in $W^{1,\tilde{p}}(\Omega)$. Hence, $\widetilde{W}(t, \nabla u_{\min}(t, z + h\sigma\eta))$ converges strongly in $L^{\tilde{p}}(\Omega)$ to $\widetilde{W}(t, \nabla u_{\min}(t, z))$. Moreover, $g'(z + h\sigma\eta)\eta$ converges to $g'(z)\eta$ strongly in $L^{\tilde{p}/(\tilde{p}-2)}(\Omega)$, since $g'$ is continuous and bounded. Hence, the right-hand side in (2.31) converges to $D_z\mathcal{E}_2(t, u_{\min}(t, z), z)[\eta]$ given by (2.30). This proves that for every $(t, z) \in [0, T] \times \mathcal{Z}$
\[
D_z\mathcal{I}_2(t, z)[\eta] = \int_{\Omega} \int_{0}^{1} g'(z)\eta \widetilde{W}(t, \nabla u_{\min}(t, z)) d\sigma dx \quad \text{for all } \eta \in \mathcal{Z},
\]
whence (2.28). Relying on (2.8), which in particular yields that $f'$ is Lipschitz continuous on $\mathbb{R}$, on (2.10), and on (2.16), we easily deduce the estimate
\[
\|D_z\mathcal{I}(t, z)\|_{\mathcal{Z}^*} \leq C \left(1 + \|z\|_{\mathcal{Z}} + \|u_{\min}\|_{H^1(\Omega)}^2\right).
\]
Then, (2.29) ensues from estimate (2.17).

**Lemma 2.8** (Lipschitz continuity of $D_z\mathcal{I}$).

Let $s = d/2$. Assume (2.1), (2.8)-(2.10) and (2.16), and set
\[
\mathcal{I}(t, z) := \mathcal{I}_2(t, z) + \int_{\Omega} f(z) dx \quad \text{for all } (t, z) \in [0, T] \times \mathcal{Z}.
\]

For every $r \in (\frac{3p}{p+2}, +\infty)$ (where $p$ is as in (2.14)), there exists a constant $c_7 > 0$ depending on $r$, $\|f\|_{C^1([0, T]; W^{-1,r}_T(\Omega))}$ and $\|u_D\|_{C^1([0, T]; W^{1,p}(\Omega))}$, such that for all $t_i \in [0, T]$ and $z_i \in \mathcal{Z}$, $i = 1, 2$, we have
\[
\|D_z\mathcal{I}(t_1, z_1) - D_z\mathcal{I}(t_2, z_2)\|_{L^r(\Omega)} \leq c_7 |t_1 - t_2| + \|z_1 - z_2\|_{L^r(\Omega)}
\]
with $\sigma = \frac{rp}{p + 2} \in (1, +\infty)$ and $\sigma'$ its conjugate exponent. In particular, there exists a constant $c_8$ depending on $c_7$ and $r$ such that
\[
\|D_z\mathcal{I}(t_1, z_1) - D_z\mathcal{I}(t_2, z_2)\|_{\mathcal{Z}^*} \leq c_8 (|t_1 - t_2| + \|z_1 - z_2\|_{L^r(\Omega)}).
\]
Hence,
\[
\text{if } t_n \to t \text{ and } z_n \to z \text{ weakly in } \mathcal{Z}, \text{ then } D_z\mathcal{I}(t_n, z_n) \to D_z\mathcal{I}(t, z) \text{ strongly in } \mathcal{Z}^*.
\]

**Proof.** Since $f'$ is Lipschitz, in order to prove estimate (2.35) it remains to investigate the properties of $D_z\mathcal{I}_2$, given by (2.28). For $i = 1, 2$, let $u_i := u_{\min}(t_i, z_i) \in W^{1,p}(\Omega)$. For every fixed $r \in (\frac{3p}{p+2}, +\infty)$, set $\tilde{p} = \frac{rp}{p+2}$, and notice that $2 < \frac{3p}{p+1} < \tilde{p} < p$, and that $r = \frac{rp}{p - \tilde{p}} > \frac{p}{p - 2}$. Hence, the exponent $\sigma$ defined by
For the last estimate we have used (2.17) and (2.20), and (2.34) follows. Since for every inequality, and relying on the Lipschitz continuity of $f$, it is sufficient to observe that for any $\sigma \in (1, \infty)$ the space $Z$ is embedded in $L^\sigma(\Omega)$, hence $L^\sigma(\Omega) \subset Z^*$, we finally arrive at (2.35). Observe that the constant $c_8$ also depends on the embedding constant for $L^\sigma(\Omega) \subset Z^*$, and thus ultimately on $r$. □

**Corollary 2.9** (Fréchet differentiability of $I$).

Let $s = d/2$. Under assumptions (2.1), (2.8)–(2.10) and (2.16), the functional $I$ is Fréchet differentiable on $[0, T] \times Z$ with a Lipschitz continuous derivative, i.e. $I \in C^{1,1}([0, T] \times Z, \mathbb{R})$. Furthermore, $\tilde{I}$ (defined in (2.33)), $\partial_t I$ and $D_2 I$ are weakly continuous and $I$ is weakly lower semicontinuous, i.e.

\[
\begin{align*}
\lim_{n \to \infty} I(t_n, z_n) &\geq I(t, z), \\
\tilde{I}(t_n, z_n) &\to \tilde{I}(t, z), \\
\partial_t I(t_n, z_n) &\to \partial_t I(t, z), \\
D_2 I(t_n, z_n) &\to D_2 I(t, z) \quad \text{weakly in } Z^*.
\end{align*}
\]

Proof. This follows from the previous Lemmata 2.6 and 2.8. Notice that the continuity property (2.38) of $\partial_t I$ and $D_2 I$ is an immediate consequence of estimates (2.27) and (2.35), joint with the compact embedding of $Z$ in $L^\sigma(\Omega)$. □

A further consequence of Lemma 2.8 is that $D_2 I$ fulfills a “generalized” monotonicity property.

**Corollary 2.10.**

Let $s = d/2$. Under assumptions (2.1), (2.8)–(2.10) and (2.16), for every $r \in \left(\frac{2p}{p-2}, +\infty\right)$ (where $p$ is as in (2.14)), there exist constants $c_9, c_{10} > 0$ such that for all $t \in [0, T]$ and $z_i \in Z$, $i = 1, 2$, we have

\[
\|z_1 - z_2\|_{L^2(\Omega)}^2 + \langle D_2 I(t, z_1) - D_2 I(t, z_2), z_1 - z_2 \rangle_Z \geq c_9 \|z_1 - z_2\|_Z^2 - c_{10} \|z_1 - z_2\|^2_{L^2(\Omega)}. \tag{2.39}
\]

Proof. It is sufficient to observe that for any $r \in \left(\frac{2p}{p-2}, +\infty\right)$ there holds

\[
\|z_1 - z_2\|_{L^2(\Omega)}^2 + \langle D_2 I(t, z_1) - D_2 I(t, z_2), z_1 - z_2 \rangle_Z \geq \|z_1 - z_2\|_Z^2 - c_9 \|z_1 - z_2\|_Z \|z_1 - z_2\|_{L^r(\Omega)},
\]

where $\tilde{I}$ is defined as in (2.33). Then, (2.39) follows upon using that $Z \in L^r(\Omega) \subset L^2(\Omega)$, and the well-known fact that for every $\eta > 0$ there exists $C_\eta > 0$ such that for all $z \in Z$ we have $\|z\|_{L^r(\Omega)} \leq \eta \|z\|_Z + C_\eta \|z\|_{L^2(\Omega)}$. □
2.4 Improved estimates under special conditions

If the boundary of \( \Omega \) is smooth and if the coefficients \( g(z)C \) in the elastic energy functional \((2.11)\) are continuous on \( \overline{\Omega} \), then the previous estimates \((2.20)\), \((2.27)\), and \((2.35)\) can be refined. These improvements will be relevant for the uniqueness analysis of the viscous problem, see Section 3.2.

Throughout this section, in addition to \((2.1)\) and \((2.9a)\) we suppose that

\[
\Omega \subset \mathbb{R}^d, \quad d \in \{2, 3\}, \quad \text{is a bounded domain with } C^1\text{-boundary } \partial \Omega
\]

and Dirichlet boundary \( \Gamma_D = \partial \Omega \).

\[
s > \frac{d}{2}.
\]

Observe that \((2.41)\) implies

\[
\mathcal{Z} \in C^{\alpha, \alpha}(\overline{\Omega}) \quad \text{for some } \alpha \in (0, 1].
\]

We shall then also require that, for the same \( \alpha \in (0, 1] \),

\[
C \in C^{\alpha, \alpha}(\overline{\Omega}, \text{Lin}(\mathbb{R}_d^{dxd}, \mathbb{R}_d^{dxd})).
\]

Under these conditions, we may apply to the linear elliptic operator \( L_z(u) = -\text{div}(g(z)C\varepsilon(u)) \) (cf. \((2.13)\)) a \( W^{1,p}\)-regularity result for weak solutions of partial differential equations on smooth domains, see e.g. [Giu03, Section 10.4]. Adapted to our situation it reads:

for every \( p \in [2, \infty) \) the operator \( L_z : W^{1,p}_0(\Omega; \mathbb{R}^d) \to W^{1,p}_0(\Omega; \mathbb{R}^d)^* \) is an isomorphism,

\[(2.44)\]

and the operator-norm of \( L_z^{-1} \) depends uniformly on the ellipticity constant \( \gamma_0 \), and on the H"older-norm of \( C \) and of \( g(z) \) (thus, ultimately, on \( \|z\|_z \) in view of \((2.42)\)).

In this setting, we have the following improved estimates.

Proposition 2.11. In addition to \((2.1)\), \((2.8)\)--\((2.10)\), assume \((2.40)\), \((2.41)\), and \((2.43)\). Let \( p \in (2, \infty) \) be fixed, and suppose that \((2.16)\) holds for the index \( p \). Then, the estimates in Lemmatas 2.4--2.8 are valid, with constants depending uniformly on \( \|z\|_z \). In particular, for \( p = 4 \) there holds: for all \( M > 0 \) there exist positive constants \( \tilde{c}_0 = \tilde{c}_0(M) \), \( \tilde{c}_3 = \tilde{c}_3(M) \), such that

\[
\forall (t, z) \in [0, T] \times \mathcal{Z}, \quad \|z\|_z \leq M : \quad \|u_{\min}(t, z)\|_{W^{1,4}_D(\Omega)} \leq \tilde{c}_0 \left( \|t\|_{W^{1,4}_D(\Omega)} + \|u_D(t)\|_{W^{1,4}(\Omega)} \right); \tag{2.45}
\]

\[
\forall (t_i, z_i) \in [0, T] \times \mathcal{Z}, \quad \|z_i\|_z \leq M, \ i = 1, 2 : \quad \|u_{\min}(t_1, z_1) - u_{\min}(t_2, z_2)\|_{W^{1,4}_D(\Omega)} \leq \tilde{c}_3 \left( |t_1 - t_2| + \|z_1 - z_2\|_z \right) \left( \|t\|_{C^1([0,T];W^{1,4}_D(\Omega))} + \|u_D(t)\|_{C^1([0,T];W^{1,4}(\Omega))} \right); \tag{2.46}
\]

Proof. Estimate \((2.45)\) can be proved by the very same argument as for \((2.17)\), relying on \((2.44)\) for \( p = 4 \). Estimate \((2.46)\) can be obtained as in the proof of Lemma 2.5, up to the following changes: One chooses \( \tilde{p} = 4 \) in \((2.22)\), and \( p = \tilde{p} = 4 \) and \( r = \infty \) in \((2.23)\) and \((2.24)\). \( \square \)

3 The viscous problem

The viscous approximation. Recall that \( \mathcal{R}_\varepsilon = \mathcal{R}_1 + \mathcal{R}_2, \) with \( \mathcal{R}_2, \varepsilon(\eta) = \frac{\varepsilon}{2} \|\eta\|_{L^2(\Omega)}^2 \), denotes the viscous dissipation functional, and \( \partial \mathcal{R}_\varepsilon : \mathcal{Z} \rightrightarrows \mathcal{Z}^* \) is its subdifferential (in the sense of convex analysis),
in the duality between $\mathcal{Z}^*$ and $\mathcal{Z}$, cf. with (1.4). Throughout this section, we shall analyze the viscous doubly nonlinear evolution equation

$$\partial \mathcal{R}_\varepsilon(z'(t)) + D_2\mathcal{I}(t, z(t)) \ni 0 \quad \text{in} \quad \mathcal{Z}^* \quad \text{for a.a.} \; t \in (0, T),$$

with the initial condition, featuring $z_0 \in \mathcal{Z}$,

$$z(0) = z_0. \tag{3.2}$$

We shall denote by $\mathcal{R}_\varepsilon^*$ the convex conjugate of the functional $\mathcal{R}_\varepsilon$, taken in the $\mathcal{Z} - \mathcal{Z}^*$ duality, viz.

$$\mathcal{R}_\varepsilon^*(\sigma) = \sup \{ \langle \sigma, \eta \rangle_{\mathcal{Z}} - \mathcal{R}_\varepsilon(\eta) : \eta \in \mathcal{Z} \}.$$ 

The following lemma collects, for later use, two crucial formulae for $\partial \mathcal{R}_\varepsilon$ and $\mathcal{R}_\varepsilon^*$.

**Lemma 3.1.** There holds

$$\partial \mathcal{R}_\varepsilon(\eta) = \partial \mathcal{R}_1(\eta) + \partial \mathcal{R}_{2,\varepsilon}(\eta) = \partial \mathcal{R}_1(\eta) + \varepsilon \eta \quad \text{for all} \; \eta \in \mathcal{Z};$$

$$\mathcal{R}_\varepsilon^*(\sigma) = \inf_{\mu \in \partial \mathcal{R}_1(0)} \frac{1}{\varepsilon} \mathcal{R}_2(\sigma - \mu) = \frac{1}{\varepsilon} \min_{\mu \in \partial \mathcal{R}_1(0)} \mathcal{R}_2(\sigma - \mu)$$

with

$$\mathcal{R}_2(\sigma) := \begin{cases} \frac{1}{2} \| \sigma \|_{L^2(\Omega)}^2 & \text{if} \; \sigma \in L^2(\Omega), \\ +\infty & \text{if} \; \sigma \in \mathcal{Z}^* \setminus L^2(\Omega). \end{cases} \tag{3.4}$$

**Proof.** The first identity in (3.3) follows from [AE84, Cor. IV.6]. Next, we observe $\partial \mathcal{R}_{2,\varepsilon}(\eta) = \{ D\mathcal{R}_{2,\varepsilon}(\eta) \}$, as $\mathcal{R}_{2,\varepsilon}$ is Fréchet differentiable on $\mathcal{Z}$. On account for (2.7), $D\mathcal{R}_{2,\varepsilon}$ coincides with the Fréchet derivative of $\mathcal{R}_{2,\varepsilon}$ in the $L^2(\Omega)$-topology, whence the second identity in (3.3).

The inf – sup convolution formula (see, e.g., [IT79, Theorem 3.3.4.1]), for $\mathcal{R}_\varepsilon^*$ yields

$$\mathcal{R}_\varepsilon^*(\sigma) = \inf \{ \mathcal{R}_{2,\varepsilon}^*(\sigma - \mu) : \mu \in \partial \mathcal{R}_1(0) \}$$

whence the first identity in (3.4). Using that $\partial \mathcal{R}_1(0) \subset \mathcal{Z}^*$ is weakly closed, it can be easily checked that the inf is in fact a min. \hfill \Box

As a consequence of (3.3) and of (2.28), the doubly nonlinear evolution equation (3.1) reads

$$\partial \mathcal{R}_\varepsilon(z'(t)) + \varepsilon z'(t) + A_\varepsilon(z(t)) + f'(z(t)) + g'(z(t))W(t, \nabla u_{\text{min}}(t, z(t))) \ni 0 \quad \text{for a.a.} \; t \in (0, T). \tag{3.5}$$

Finally, for later convenience we observe that, by the 1-positive homogeneity of $\mathcal{R}_1$, its convex analysis subdifferential $\partial \mathcal{R}_1$ satisfies the following relations for every $v \in \mathcal{Z}$:

$$\eta \in \partial \mathcal{R}_1(v) \Rightarrow \begin{cases} \langle \eta, v \rangle_{\mathcal{Z}} = \mathcal{R}_1(v), \\ \langle \eta, w \rangle_{\mathcal{Z}} \leq \mathcal{R}_1(w) \quad \text{for all} \; w \in \mathcal{Z}. \end{cases} \tag{3.6}$$

### 3.1 Existence and a priori estimates for viscous solutions

The following result clarifies the properties of solutions to (3.1) (equivalently, of (3.5)), with the regularity $z \in H^1(0, T; \mathcal{Z})$.

**Proposition 3.2.** Let $s = d/2$. Assume (2.1), (2.8)–(2.10), and (2.16). Then, for a curve $z \in H^1(0, T; \mathcal{Z})$ the following are equivalent:

1. $z$ is a solution to (3.1);
2. $z$ fulfills for all $0 \leq s \leq t \leq T$ the energy identity
\[
\int_s^t \mathcal{R}_e(z'(\tau))d\tau + \int_s^t \mathcal{R}_e^*(-D_z\mathcal{I}(\tau,z(\tau)))d\tau + \mathcal{I}(t,z(t)) = \mathcal{I}(s,z(s)) + \int_s^t \partial_t \mathcal{I}(\tau,z(\tau))d\tau; \tag{3.7}
\]

3. $z$ fulfills for all $0 \leq t \leq T$ the energy inequality
\[
\int_0^t \mathcal{R}_e(z'(\tau))d\tau + \int_0^t \mathcal{R}_e^*(-D_z\mathcal{I}(\tau,z(\tau)))d\tau + \mathcal{I}(t,z(t)) \leq \mathcal{I}(0,z(0)) + \int_0^t \partial_t \mathcal{I}(\tau,z(\tau))d\tau. \tag{3.8}
\]

**Proof.** We start by observing the following crucial fact: For every $z \in H^1(0,T;\mathcal{Z})$, there holds $D_z\mathcal{I}(\cdot,z(\cdot)) \in L^\infty(0,T;\mathcal{Z}^*)$ (thanks to (2.29)), and Corollary 2.9 guarantees the chain rule identity
\[
\frac{d}{dt}\mathcal{I}(t,z(t)) = \partial_t \mathcal{I}(t,z(t)) + \langle D_z\mathcal{I}(t,z(t)),z'(t)\rangle_{\mathcal{Z}} \quad \text{for a.a. } t \in (0,T). \tag{3.9}
\]

Clearly, (3.7) implies (3.8). Suppose now that $z$ fulfills (3.8): applying (3.9) we have that
\[
\mathcal{I}(0,z(0)) + \int_0^t \partial_t \mathcal{I}(\tau,z(\tau))d\tau = \mathcal{I}(t,z(t)) + \int_0^t \langle -D_z\mathcal{I}(\tau,z(\tau)),z'(\tau)\rangle_{\mathcal{Z}} d\tau.
\]

Taking into account the elementary convex analysis inequality $\langle \xi,v\rangle_{\mathcal{Z}} \leq \mathcal{R}_e(v) + \mathcal{R}_e^*(\xi)$ for all $z \in \mathcal{Z}$, $\zeta \in \mathcal{Z}^*$, we immediately conclude that the above integral inequality indeed holds as an equality, in fact pointwise
\[
\mathcal{R}_e(z'(t)) + \mathcal{R}_e^*(-D_z\mathcal{I}(t,z(t))) = \langle -D_z\mathcal{I}(t,z(t)),z'(t)\rangle_{\mathcal{Z}} = 0 \quad \text{for a.a. } t \in (0,T).
\]

Again by convex analysis, from the above relation we infer that $-D_z\mathcal{I}(t,z(t)) \in \partial \mathcal{R}_e(z'(t))$ for almost all $t \in (0,T)$, i.e. $z$ is a solution to (3.1).

Suppose now that $z$ fulfills (3.1), test it by $z'(t)$, and use for every $\xi(t) \in \partial \mathcal{R}_e(z'(t))$ the convex analysis identity $\langle \xi(t),z'(t)\rangle_{\mathcal{Z}} = \mathcal{R}_e(z'(t)) + \mathcal{R}_e^*(\xi(t))$ for a.a. $t \in (0,T)$. Then, (3.7) follows upon applying the chain rule (3.9), and integrating on $(s,t)$ for all $0 \leq s \leq t$.

We may now state our main result on the viscous problem (3.1).

**Theorem 3.3.** Let $s = d/2$. Assume (2.1), (2.8)-(2.10), and (2.16). Suppose that the initial datum $z_0 \in \mathcal{Z}$ additionally fulfills
\[
D_z\mathcal{I}(0,z_0) \in L^2(\Omega). \tag{3.10}
\]

Then,

1. for every $\epsilon > 0$ there exists a viscous solution $z_\epsilon \in H^1(0,T;\mathcal{Z})$ to the Cauchy problem (3.1)-(3.2), satisfying for all $0 \leq s \leq t \leq T$ the energy identity
\[
\int_s^t (\mathcal{R}_1^*(z'_\epsilon(\tau)) + \epsilon \mathcal{R}_2^*(z'_\epsilon(\tau))) + \min_{\mu \in \partial \mathcal{R}_1(0)} \mathcal{R}_2(-D_z\mathcal{I}(\tau,z_\epsilon(\tau)) - \mu)) d\tau + \mathcal{I}(t,z_\epsilon(t)) = \mathcal{I}(s,z_\epsilon(s)) + \int_s^t \partial_t \mathcal{I}(\tau,z_\epsilon(\tau))d\tau; \tag{3.11}
\]

2. There exists a family of viscous solutions $(z_\epsilon)_{\epsilon > 0}$ and a constant $C_0 > 0$ such that
\[
\sup_{\epsilon > 0} \int_0^T \|z'_\epsilon(\tau)\|^2_{\mathcal{Z}} d\tau \leq C_0. \tag{3.12}
\]

16
Outlook to the proof of Theorem 3.3. The proof will be developed in Section 4 working on the time-discretization scheme associated with (3.1).

First, we will prove for the approximate solutions \((\tilde{z}_\tau)\) (obtained through linear interpolation of the discrete solutions with time-step \(\tau\); we omit to highlight in the notation their dependence on \(\epsilon\)), the estimate \(\sup_\tau \|\tilde{z}_\tau\|_{H^1(0,T;Z)} \leq C(\epsilon)\), with \(C(\epsilon)\) depending on \(\epsilon > 0\) and exploding as \(\epsilon \to 0\). Second, for \((\hat{z}_\tau)\), we will obtain an estimate in \(BV([0,T]; Z)\), for a constant independent of \(\epsilon\).

Furthermore, arguing on the time-discrete approximation of (3.1), we shall prove the following remarkable fact (cf. Proposition 4.5): Under special conditions, if \(d = 2\) and if the initial datum \(z_0\) fulfills \(z_0(x) \in [0,1]\) for a.a. \(x \in \Omega\), then there exist viscous solutions \(z_\tau\) with \(z_\tau(x) \in [0,1]\) for a.a. \(x \in \Omega\).

Remark 3.4 (A different approach to the proof of Theorem 3.3). As an alternative to the time-discretization scheme for (3.1), one might consider the “augmented” viscous dissipation for \(\eta \in Z\)

\[
R_{\epsilon,\delta}(\eta) := R_{\epsilon}(\eta) + R_{Z,\eta}(\eta) = R_1(\eta) + R_{Z,\delta}(\eta) + R_{Z,\eta}(\eta) \quad \text{with} \quad R_{Z,\eta}(\eta) = \frac{\delta}{2} \|\eta\|^2_{Z},
\]

where \(\|\eta\|_{Z} := \sqrt{a_\delta(\eta,\eta)}\) denotes the semi-norm on \(Z\) induced by the bilinear form \(a_\delta\) and \(\delta > 0\). This approach was developed in detail in [KRZ11, Sec. 4]. The arguments to prove Theorem 3.3 are slightly shorter compared to the proof via time-discretization. However, in view of further developments in the direction of numerical analysis we have confined ourselves to the approach via time-discretization. Moreover, let us stress that in the special framework of Prop. 4.5, time-discretization brings about additional information. If the solutions to the Cauchy problem (3.1)–(3.2) are unique (see Section 3.2 for sufficient conditions), then the solutions arising as limits of the time-discrete scheme, and the solutions as limits of the \(\delta\)-viscous problem as \(\delta \to 0\), do coincide.

Remark 3.5 (Results under the sole condition \(z_0 \in Z\)). As it will be clear from the discussion in Section 4 (cf. Remark 4.4), we are not able to prove existence of viscous solutions under the sole condition \(z_0 \in Z\). Indeed, with the latter condition, and standard energy estimates in the time-discrete approximate problem, we can prove that there exists \(z_\tau \in L^\infty(0,T;Z) \cap H^1(0,T;L^2(\Omega))\) with \(z_\tau(0) = z_0\), fulfilling the energy inequality (3.8) for all \(0 \leq t \leq T\). However, without the additional condition (3.10), we are not able to obtain the further regularity \(z_\tau \in H^1(0,T;Z)\) (viz., the higher spatial regularity \(z_\tau' \in L^2(0,T;Z)\) for \(z_\tau'\)). On the other hand, only such a regularity ensures the validity of the chain rule (3.9), and (3.9) is the key point for deducing, from (3.8), that \(z_\tau\) in fact fulfills (3.1), cf. the proof of Proposition 3.2.

3.2 Uniqueness for the viscous problem under special conditions

In the setting of Proposition 2.11, we have the following uniqueness result for viscous solutions.

Proposition 3.6 (Uniqueness for viscous solutions). In addition to (2.1), (2.8)–(2.10), assume (2.40), (2.41), and (2.43). Suppose further that for \(i \in \{1,2\}\) the data \((u_D^i,\ell^i)\) satisfy (2.16) for \(p = 4\), and that for \(z_0^1 \in Z\) it holds \(D_z^1T(0,z_0^1) \in L^2(\Omega)\). Let \(z_1, z_2 \in H^1(0,T;Z)\) be solutions to (3.1), supplemented with the data \((u_D^1,\ell^1)\) and \((u_D^2,\ell^2)\), respectively. Set \(M = \sum_{i=1}^2 \|z_i\|_{L^\infty(0,T;Z)}\). Then, there exists a constant \(C_1 > 0\), depending on \(M\), on \(T\), and on \(\tau_2\) (cf. (2.10)), such that for almost all \(t \in (0,T)\) it holds

\[
\|z_1(t) - z_2(t)\|_{Z} + \sqrt{\epsilon} \|z'_1 - z'_2\|_{L^2(0,T;L^2(\Omega))} \leq C_1 \left( \|z_0^1 - z_0^2\|_{Z} + \|u_D - u_D^2\|_{L^2(0,T;W^{1,4}(\Omega))} + \|\ell^1 - \ell^2\|_{L^2(0,T;W^{-1,4}_*\Omega))} \right). \quad (13.13)
\]

Proof. We subtract the differential inclusion (3.1) for \(z_2\) from (3.1) for \(z_1\), and we use \(z'_1 - z'_2\) as test function. Taking into account that, by monotonicity, \(\langle \partial R_1(z'_1(t)) - \partial R_1(z'_2(t)), z'_1(t) - z'_2(t) \rangle_z \geq 0\) for
almost all \( t \in (0, T) \) (where with abuse of notation we have written \( \partial R_1 \) as single-valued), we arrive at the following inequality
\[
\langle e(z_1'(t) - z_2'(t)) + D_zI(t, z_1(t)) - D_zI(t, z_2(t)), z_1'(t) - z_2'(t) \rangle_{E} \leq 0 \quad \text{for a.a.} \ t \in (0, T)
\]
We rearrange the terms, and add and subtract \( \langle z_1(t) - z_2(t), z_1'(t) - z_2'(t) \rangle_{E} \). Thus,
\[
\epsilon \|z_1(t) - z_2(t)\|^2_{L^2(\Omega)} + \frac{1}{2} \frac{d}{dt} \|z_1(t) - z_2(t)\|^2_{L^2(\Omega)} + \frac{1}{2} \frac{d}{dt} \|z_1(t) - z_2(t)\|^2_{L^2(\Omega)}
\leq - \int_{\Omega} (f'(z_1(t)) - f'(z_2(t))) (z_1'(t) - z_2'(t)) dx
\]
\[
- \int_{\Omega} (G_1(t) - G_2(t))(z_1'(t) - z_2'(t)) dx \doteq S_1 + S_2,
\]
where we have used the short-hand notation \( G_i(t) := g'(z_i(t))\bar{W}(t, \nabla u_{\min}(t, z_i(t))) \), and \( u_{\min}(t, z_i(t)) \) is the minimizer of \( E_i(t; \cdot, z_i(t)) \) with the data \( u_D^i(t) \), \( \ell^i(t) \).

Now, for almost all \( t \in (0, T) \) the following estimate holds
\[
\|G_1(t) - G_2(t)\|^2_{L^2(\Omega)} \leq 2 \int_{\Omega} |g'(z_1(t)) - g'(z_2(t))|^2 \bar{W}(t, \nabla u_{\min}(t, z_1(t)))^2 dx
\]
\[
+ 2 \|g(z_1(t))\|^2_{L^\infty(\Omega)} \|u_{\min}(t, z_1(t))\|^4_{W^{1,4}(\Omega)} + \|u_D(t)\|^4_{W^{1,4}(\Omega)}
\]
\[
+ C' \|g(z_2(t))\|^2_{L^\infty(\Omega)} \|u_{\min}(t, z_1(t)) + u_{\min}(t, z_2(t))\|^2_{W^{1,4}(\Omega)} + \|u_D^1(t) + u_D^2(t)\|^2_{W^{1,4}(\Omega)}
\]
\[
\times \left( \|u_{\min}(t, z_1(t)) - u_{\min}(t, z_2(t))\|^2_{W^{1,4}(\Omega)} + \|u_D^1(t) - u_D^2(t)\|^2_{W^{1,4}(\Omega)} \right)
\]
where the second inequality follows from (2.10) and Hölder’s inequality, and the last one from the estimate
\[
\|u_{\min}(t, z_1(t)) - u_{\min}(t, z_2(t))\|_{W^{1,4}(\Omega)}
\]
\[
\leq \|u_{\min}(t, z_1(t), \ell^1(t), u_D^1(t)) - u_{\min}(t, z_1(t), \ell^2(t), u_D^2(t))\|_{W^{1,4}(\Omega)}
\]
\[
+ \|u_{\min}(t, z_2(t), \ell^1(t), u_D^2(t)) - u_{\min}(t, z_2(t), \ell^2(t), u_D^2(t))\|_{W^{1,4}(\Omega)}
\]
\[
\leq C' (M, \gamma_2) \left( \|z_1(t) - z_2(t)\|_E + \|\ell^1(t) - \ell^2(t)\|_{W^{1,4}(\Omega)} \right)
\]
for some \( C' (M, \gamma_2) \), which follows from (2.45) and (2.46). Notice that the constants \( C(M, \gamma_2) \) and \( C'(M, \gamma_2) \) depend on \( M \) and on \( \gamma_2 \).

Then, also taking into account that \( f' \) is Lipschitz continuous, the terms \( S_1 \) and \( S_2 \) on the right-hand side of (3.14) can be estimated via
\[
|S_1| \leq \epsilon \frac{d}{dt} \|z_1(t) - z_2(t)\|^2_{L^2(\Omega)} + C \|z_1(t) - z_2(t)\|^2_{L^2(\Omega)}
\]
\[
|S_2| \leq \epsilon \frac{d}{dt} \|z_1(t) - z_2(t)\|^2_{L^2(\Omega)} + C \|G_1(t) - G_2(t)\|^2_{L^2(\Omega)}
\]
\[
\leq \epsilon \frac{d}{dt} \|z_1(t) - z_2(t)\|^2_{L^2(\Omega)}
\]
\[
+ C \left( \|z_1(t) - z_2(t)\|^2_{L^2(\Omega)} + \|\ell^1(t) - \ell^2(t)\|^2_{W^{1,4}(\Omega)} + \|u_D^1(t) - u_D^2(t)\|^2_{W^{1,4}(\Omega)} \right).
\]

18
Now, we integrate (3.14) on $(0, t)$, and, taking into account all of the above calculations, conclude
\[
\frac{\epsilon}{2} \|z_1^t - z_2^t\|_{L^2(0, t; L^2(\Omega))}^2 + c \|z_1(t) - z_2(t)\|_Z^2 \\
\leq C \|z_1^0 - z_2^0\|_Z^2 + C \int_0^t \left( \|z_1(\tau) - z_2(\tau)\|_Z^2 + \|\ell_1(\tau) - \ell_2(\tau)\|_{W^{-1,4}_D(\Omega)}^2 + \|u_1^\tau(\tau) - u_2^\tau(\tau)\|_{W^{1,4}_D(\Omega)}^2 \right) \, d\tau.
\]
Gronwall’s inequality (cf. e.g. [Bre73, Lemma A.4]) finally yields (3.13).

We conclude this section with the following corollary of Proposition 3.6.

**Theorem 3.7.** In addition to (2.1), (2.8)–(2.10), assume (2.40), (2.41), (2.43), and that (2.16) holds for $p = 4$. Then, for every initial datum $z_0 \in \mathcal{Z}$ fulfilling (3.10), there exists a unique solution $z \in H^1(0, T; \mathcal{Z})$ to the Cauchy problem for (3.1).

## 4 Time-discrete viscous approximation and uniform estimates

In this section, we shall prove Theorem 3.3 by passing to the limit in the time-discretization scheme which we set up below. First, in Section 4.1 we show the existence of viscous solutions. Next, in Section 4.2 we prove the $BV$-estimate (3.12).

Throughout this section, we omit the dependence of the discrete solutions on $\epsilon > 0$, and only highlight their dependence on the fineness of the non-constant time-steps.

**Time-incremental problem.** We consider the following time-discrete incremental minimization problem: Given $\epsilon > 0$, $z_0 \in \mathcal{Z}$ and a partition $\{0 = t_0^\tau < \ldots < t_N^\tau = T\}$ of the time interval $[0, T]$ with fineness $\tau = \sup_{0 \leq k \leq N} (t_{k+1}^\tau - t_k^\tau)$, the elements $(z_k^\tau)_{0 \leq k \leq N}$ are determined through $z_0^\tau = z_0$ and
\[
z_{k+1}^\tau \in \text{Argmin} \left\{ I(t_{k+1}^\tau, z) + \tau_k \mathcal{R}_\epsilon \left( \frac{z - z_k^\tau}{\tau_k} \right) : z \in \mathcal{Z} \right\}.\tag{4.1}
\]
Here, $\tau_k = t_{k+1}^\tau - t_k^\tau$ and $\mathcal{R}_\epsilon$ is defined in (1.9). The existence of minimizers follows with the direct method in the calculus of variations, thanks to the properties of the reduced energy $I$ formulated in Section 2.3. Relying on Corollary 2.10, it can be easily shown that, indeed, the minimum problem (4.1) has a unique solution provided that $\tau$ is small enough.

We point out that any family $(z_1^\tau, \ldots, z_N^\tau) \subset \mathcal{Z}$ of minimizers of the incremental problem (4.1) satisfy for all $k \in \{0, \ldots, N - 1\}$ the discrete Euler-Lagrange equation
\[
\partial_\mathcal{R}_1 \left( \frac{z_{k+1}^\tau - z_k^\tau}{\tau_k} \right) + \epsilon \frac{z_{k+1}^\tau - z_k^\tau}{\tau_k} + D_z I(t_{k+1}^\tau, z_{k+1}^\tau) \ni 0, \tag{4.2}
\]
also taking into account (3.3).

**Notation 4.1.** The following piecewise constant and piecewise linear interpolation functions will be used in the sequel:
\[
\pi_\tau (t) = z_{k+1}^\tau \quad \text{for } t \in (t_k^\tau, t_{k+1}^\tau],
\]
\[
\bar{z}_\tau (t) = z_k^\tau \quad \text{for } t \in [t_k^\tau, t_{k+1}^\tau),
\]
\[
\hat{z}_\tau (t) = z_k^\tau + \frac{t - t_k^\tau}{\tau_k} (z_{k+1}^\tau - z_k^\tau) \quad \text{for } t \in [t_k^\tau, t_{k+1}^\tau].
\]
Furthermore, we shall use the notation
\[
\tau(r) = \tau_k \text{ for } r \in (t_k^\tau, t_{k+1}^\tau), \quad \tau(r) = t_{k+1}^\tau \text{ for } r \in (t_k^\tau, t_{k+1}^\tau), \quad \tau(r) = t_k^\tau \text{ for } r \in [t_k^\tau, t_{k+1}^\tau].
\]
Clearly,
\[ \tau_r(t), \xi_r(t) \to t \quad \text{as } \tau \to 0 \text{ for all } t \in [0, T]. \] (4.3)

Moreover, for any given function \( b \) which is piecewise constant on the intervals \((t_k^r, t_{k+1}^r)\) we set
\[ \triangle_{\tau(r)} b(r) = b(r) - b(s) \text{ for } r \in (t_k^r, t_{k+1}^r) \text{ and } s \in (t_{k-1}^r, t_k^r). \]

With the above notation, (4.2) can be reformulated as
\[ \partial \mathcal{R}_1(\hat{z}_r'(t)) + \epsilon \hat{z}'_r(t) + D_z \mathcal{I}(\tau_r(t), \tau_r(t)) \ni 0 \quad \text{for a.a. } t \in (0, T). \] (4.4)

### 4.1 Existence of viscous solutions

The following result states the crucial a priori estimate on the approximate solutions \((\hat{z}_r)_r\).

**Proposition 4.2.** Let \( s = d/2 \), and assume (2.1), (2.8)–(2.10) and (2.16). Suppose that \( z_0 \in Z \) also fulfills (3.10), viz. \( \mathcal{D}_z \mathcal{I}(0, z_0) \in L^2(\Omega) \).

Then, there exist constants \( C_{12}, C_{13} > 0 \) such that for every \( \epsilon, \tau > 0 \) the solutions of the time incremental problem (4.1) satisfy
\[
\int_0^T \| \hat{z}_r'(t) \|^2_Z \, dt \leq (1 + \epsilon^{-1} \| \mathcal{D} Z(0, z_0) \|_{L^2(\Omega)}) \exp \left( C_{12}(1 + \frac{T}{\tau}) \right),
\] (4.5)
\[
\epsilon \left\| \hat{z}_r' \left( \frac{t_i^r}{2} \right) \right\|_{L^2(\Omega)} \leq C_{13} \left( \sqrt{\epsilon} + \| \mathcal{D} Z(0, z_0) \|_{L^2(\Omega)} \right) \exp \left( \frac{C_{12} t_i^r}{\epsilon} \right),
\] (4.6)

where \( t_i^r \) is the first non-zero node of the partition of \([0, T]\).

**Proof.** Let \( \tau > 0 \) and let \( \{z_1^r, \ldots, z_N^r\} \subset Z \) be minimizers of the incremental problem (4.1). For \( t \in (t_k^r, t_{k+1}^r) \) we define \( \tau_r(t) := \epsilon \hat{z}_r'(t) + A_s \tau_r(t) + D_z \tilde{I}(\tau_r(t), \tau_r(t)) \), where \( \tilde{I} \) as in (2.33). Hence, relation (4.4) is equivalent to \(-\tau_{\tau}(t) \in \partial \mathcal{R}_1(\hat{z}_r'(t)) \) for \( t \in (t_k^r, t_{k+1}^r) \). From the 1-homogeneity of \( \mathcal{R}_1 \) using (3.6) we deduce
\[
\forall t \in (t_k^r, t_{k+1}^r) \quad -\mathcal{R}_1(\hat{z}_r'(t)) = (\tau_r(t), \hat{z}_r'(t)) \in Z,
\] (4.7)
\[
\forall t \in [0, T] \setminus \{t_0^r, \ldots, t_N^r\} \quad \mathcal{R}_1(\hat{z}_r'(t)) \geq (\tau_r(t), \hat{z}_r'(t)) \in Z.
\] (4.8)

Adding both relations and choosing \( \rho \in (t_i^r, t_{i+1}^r) \) and \( \sigma \in (t_{i-1}^r, t_i^r) \), it follows
\[
0 \geq \tau_i^{-1} (\tau_r(\rho) - \tau_r(\sigma), \hat{z}_r'(\rho)) \in Z.
\]

This relation can be rewritten as
\[
\epsilon \tau_i^{-1} (\hat{z}_r'(\rho) - \hat{z}_r'(\sigma), \hat{z}_r'(\rho))_{L^2(\Omega)} + \tau_i^{-1} (A_s (\tau_r(\rho) - \tau_r(\sigma)), \hat{z}_r'(\rho))_Z \leq -\tau_i^{-1} (D_z \tilde{I}(\tau_r(\rho), \tau_r(\rho)), D_z \tilde{I}(\tau_r(\sigma), \tau_r(\sigma)), \hat{z}_r'(\rho))_Z. \quad (4.9)
\]

Observe that \( \tau_i^{-1} (\tau_r(\rho) - \tau_r(\sigma)) = \hat{z}_r'(\rho) \), hence the second term on the left-hand side can be replaced with \( A_s (\hat{z}_r'(\rho), \hat{z}_r'(\rho)) \). Moreover, using that \( 2a(a - b) = a^2 - b^2 + (a - b)^2 \), the first term is equal to
\[
\frac{\epsilon}{\tau_i} \left( \hat{z}_r'(\rho) - \hat{z}_r'(\sigma), \hat{z}_r'(\rho) \right)_{L^2(\Omega)} = \frac{\epsilon}{2\tau_i} \left( \| \hat{z}_r'(\rho) \|_{L^2(\Omega)}^2 - \| \hat{z}_r'(\sigma) \|_{L^2(\Omega)}^2 + \| \hat{z}_r'(\rho) - \hat{z}_r'(\sigma) \|_{L^2(\Omega)}^2 \right).
\]
Next, we “integrate” (4.9) on the time interval \((\tau_{0}, t)\) (that is, we multiply both sides of (4.9) by \(\tau\) and sum for \(i = 1, \ldots, k\), assuming \(t \in (\tau_{i}, \tau_{k+1})\)). Since \(\hat{z}_{t}^{\sigma} \equiv \frac{z_{t}^{\sigma} - z_{0}^{\sigma}}{\tau_{0}}\) on \([0, \tau_{0})\), in particular \(\frac{\hat{z}_{t}^{\sigma} - z_{0}^{\sigma}}{\tau_{0}} = \hat{z}_{t}^{\sigma}(\frac{\tau}{\tau_{0}})\)

and thus, neglecting the non-negative term \(\|\hat{z}_{t}^{\sigma}(\rho) - \hat{z}_{t}^{\sigma}(\sigma)\|_{L^{2}(\Omega)}\), we obtain the estimate

\[
\frac{\epsilon}{2} \|\hat{z}_{t}^{\sigma}(t)\|_{L^{2}(\Omega)}^{2} - \frac{\epsilon}{2} \left\|\frac{\tau_{0}}{2} \right\|_{L^{2}(\Omega)}^{2} + \int_{\tau_{0}}^{\tau_{f}(t)} a_{\sigma}(\hat{z}_{t}^{\sigma}(r), \hat{z}_{t}^{\sigma}(r)) \, dr \\
\leq - \int_{\tau_{0}}^{\tau_{f}(t)} \frac{1}{\tau(r)} \langle \Delta_{\tau}(r)D_{\tau} \hat{z}(\tau_{r}(r), \tau_{r}(r)), \hat{z}_{t}^{\sigma}(r) \rangle \, dr \quad \text{for } t \in [0, T] \setminus \{\tau_{0}, \ldots, \tau_{k}\}.
\]

see Notation 4.1. Adding the squared \(L^{2}(L^{2})\)-norm of \(\hat{z}_{t}^{\sigma}\) on both sides we arrive at

\[
\frac{\epsilon}{2} \|\hat{z}_{t}^{\sigma}(t)\|_{L^{2}(\Omega)}^{2} + \int_{\tau_{0}}^{\tau_{f}(t)} \|\hat{z}_{t}^{\sigma}(r)\|_{L^{2}(\Omega)}^{2} \, dr \\
\leq \frac{\epsilon}{2} \left\|\frac{\tau_{0}}{2} \right\|_{L^{2}(\Omega)}^{2} + \int_{\tau_{0}}^{\tau_{f}(t)} \|\hat{z}_{t}^{\sigma}(r)\|_{L^{2}(\Omega)}^{2} \, dr - \int_{\tau_{0}}^{\tau_{f}(t)} \frac{1}{\tau(r)} \langle \Delta_{\tau}(r)D_{\tau} \hat{z}(\tau_{r}(r), \tau_{r}(r)), \hat{z}_{t}^{\sigma}(r) \rangle \, dr.
\]

The next goal is to derive for the right-hand side an upper bound that is independent of the time step size \(\tau\). Since by assumption we have \(D_{\tau} \mathcal{I}(0, z_{0}) \in L^{2}(\Omega)\), choosing \(t = \frac{\tau_{0}}{2}\) in (4.7) gives

\[
0 = \mathcal{R}_{1}(\hat{z}_{t}^{\sigma}(\tau_{0}/2)) + (\mathcal{I}_{r}(\tau_{0}/2), \hat{z}_{t}^{\sigma}(\tau_{0}/2)) \geq \epsilon \|\hat{z}_{t}^{\sigma}(\tau_{0}/2)\|_{L^{2}(\Omega)}^{2} + \langle \hat{z}_{t}^{\sigma}(\tau_{0}/2), \mathcal{I}_{r}(\tau_{0}/2) \rangle + \langle \mathcal{I}_{r}(\tau_{0}/2), \hat{z}_{t}^{\sigma}(\tau_{0}/2) \rangle.
\]

Hence,

\[
\epsilon \|\hat{z}_{t}^{\sigma}(\tau_{0}/2)\|_{L^{2}(\Omega)}^{2} \leq -\langle D_{\tau} \mathcal{I}(0, z_{0}), \hat{z}_{t}^{\sigma}(\tau_{0}/2) \rangle - \langle D_{\tau} \mathcal{I}(\tau_{1}), \hat{z}_{t}^{\sigma}(\tau_{0}/2) \rangle - D_{\tau} \mathcal{I}(0, z_{0}), \hat{z}_{t}^{\sigma}(\tau_{0}/2) \rangle \\
\leq \frac{1}{2\epsilon} \|D_{\tau} \mathcal{I}(0, z_{0})\|_{L^{2}(\Omega)}^{2} + \frac{\epsilon}{2} \|\hat{z}_{t}^{\sigma}(\tau_{0}/2)\|_{L^{2}(\Omega)}^{2} + \int_{0}^{\tau_{f}(t)} \|\hat{z}_{t}^{\sigma}(r)\|_{L^{2}(\Omega)}^{2} \, dr - \int_{0}^{\tau_{f}(t)} \frac{1}{\tau(r)} \langle \Delta_{\tau}(r)D_{\tau} \hat{z}(\tau_{r}(r), \tau_{r}(r)), \hat{z}_{t}^{\sigma}(r) \rangle \, dr.
\]

Absorbing the second term on the right-hand side into the term on the left-hand side, and combining the resulting estimate with (4.10) leads to

\[
\frac{\epsilon}{2} \|\hat{z}_{t}^{\sigma}(t)\|_{L^{2}(\Omega)}^{2} + \int_{0}^{\tau_{f}(t)} \|\hat{z}_{t}^{\sigma}(r)\|_{L^{2}(\Omega)}^{2} \, dr \\
\leq \frac{1}{2\epsilon} \|D_{\tau} \mathcal{I}(0, z_{0})\|_{L^{2}(\Omega)}^{2} + \int_{0}^{\tau_{f}(t)} \|\hat{z}_{t}^{\sigma}(r)\|_{L^{2}(\Omega)}^{2} \, dr - \int_{0}^{\tau_{f}(t)} \frac{1}{\tau(r)} \langle \Delta_{\tau}(r)D_{\tau} \hat{z}(\tau_{r}(r), \tau_{r}(r)), \hat{z}_{t}^{\sigma}(r) \rangle \, dr.
\]

We now derive an estimate for the last term in the same way as in (2.37) in Lemma 2.8. Indeed, for arbitrary \(\hat{p} \in (2, p)\) let \(\sigma, r \in (1, \infty)\) be defined by \(r = p\hat{p}(p - \hat{p})^{-1}\) and \(\frac{1}{\sigma} + \frac{1}{r} = 1\). Observe that \(r > 2\) and \(\sigma > 2\). Using (2.37) for \(D_{\tau}\) and the fact that \(f'\) is Lipschitz by (2.16), for a.a. \(\tau \in (0, T)\) we find that

\[
\left| \int_{0}^{\tau_{f}(t)} \langle \Delta_{\tau}(r)D_{\tau} \hat{z}(\tau_{r}(r), \tau_{r}(r)), \hat{z}_{t}^{\sigma}(r) \rangle \, dr \right| \leq C \|\hat{z}_{t}^{\sigma}(r)\|_{L^{r}(\Omega)} \left( \|\hat{z}_{t}^{\sigma}(r)\|_{L^{\sigma}(\Omega)} + 1 \right).
\]

(12)

Let \(\sigma_{0} = \max\{\sigma, r\} > 2\). Since \(s = \frac{q}{t}\), the space \(Z\) is embedded in \(L^{\sigma_{0}}(\Omega)\). Using a Gagliardo-Nirenberg type inequality for Sobolev-Slobodeckij spaces (cf. e.g. [BM01, Cor. 3.2]), it follows with a suitable \(\theta \in (0, 1)\) and \(\rho > 0\) to be chosen that

\[
\|\hat{z}_{t}^{\sigma}(r)\|_{L^{\sigma_{0}}(\Omega)}^{2} \leq c \|\hat{z}_{t}^{\sigma}(r)\|_{L^{2}(\Omega)}^{2(1-\theta)} \|\hat{z}_{t}^{\sigma}(r)\|_{L^{2}(\Omega)}^{2\theta} \leq \rho c \|\hat{z}_{t}^{\sigma}(r)\|_{L^{2}(\Omega)}^{2} + c_{\rho} \|\hat{z}_{t}^{\sigma}(r)\|_{L^{2}(\Omega)}^{2}.
\]

Therefore we obtain

\[
\left( \int_{0}^{\tau_{f}(t)} \frac{1}{\tau(r)} \langle \Delta_{\tau}(r)D_{\tau} \hat{z}(\tau_{r}(r), \tau_{r}(r)), \hat{z}_{t}^{\sigma}(r) \rangle \, dr \right) \|\hat{z}_{t}^{\sigma}(r)\|_{L^{\sigma_{0}}(\Omega)}^{2} \leq C \int_{0}^{\tau_{f}(t)} \|\hat{z}_{t}^{\sigma}(r)\|_{L^{2}(\Omega)}^{2} \, dr + \frac{1}{2} \int_{0}^{\tau_{f}(t)} \|\hat{z}_{t}^{\sigma}(r)\|_{L^{2}(\Omega)}^{2} \, dr + C'.
\]
for some positive constants $C$ and $C'$ independent of $\tau$ (and $e$). Absorbing the term $\frac{1}{2} \int_0^{\tau_0(t)} \|z'_e(r)\|^2 \, dr$ on the left-hand side of (4.11) we have finally shown that there exist constants $C > 0$ and $C' > 0$ such that for all $\tau$ and all $t \in [0,T]\{t^0_0,\ldots,t^N_N\}$ it holds

$$\frac{\epsilon}{2} \|\bar{z}'_e(t)\|_{L^2(\Omega)}^2 + \frac{1}{2} \int_0^{\tau_0(t)} \|z'_e(r)\|^2 \, dr \leq C \int_0^{\tau_0(t)} \|z'_e(r)\|^2_{L^2(\Omega)} \, dr + \frac{1}{2\epsilon} \|D_t \mathcal{I}(0, z_0)\|^2_{L^2(\Omega)} + C'. \quad (4.13)$$

Applying Gronwall’s inequality, we conclude that for all $\tau$ and all $t \in [0,T]\{t^0_0,\ldots,t^N_N\}$

$$\epsilon \|\bar{z}'_e(t)\|_{L^2(\Omega)}^2 \leq \left(C' + \frac{1}{2\epsilon} \|D_t \mathcal{I}(0, z_0)\|^2_{L^2(\Omega)}\right) \exp(C\tau(t)/\epsilon), \quad (4.14)$$

which after multiplying with $\epsilon$ and taking the root, in particular yields (4.6). Then, estimate (4.5) immediately follows from (4.13).

We can now prove the first part of Theorem 3.3, and pass to the limit in (4.4) as $\tau \to 0$.

**Theorem 4.3 (Existence of viscous solutions).** Let $s = d/2$. Assume (2.1), (2.8)–(2.10), and (2.16). Suppose that the initial datum $z_0 \in Z$ also fulfills (3.10), viz. $D_t \mathcal{I}(0, z_0) \in L^2(\Omega)$. Let $(\hat{z}_r)_{r>0} \subset H^1(0, T; Z)$ be a family of piecewise affine interpolants constructed from the solutions of (4.1) and supplemented with the initial datum $z_0$.

Then, for every sequence of fineness-parameters $(\tau^j)$ with $\tau^j \searrow 0$ as $j \to \infty$ there exists a (not relabeled) subsequence of $(\hat{z}_r)$ and $z \in H^1(0, T; Z)$ such that $z$ is a solution to the Cauchy problem (3.1)–(3.2) and the following convergences hold as $j \to \infty$:

$$\hat{z}_r^j \to z \text{ weakly in } H^1(0, T; Z), \quad (4.15)$$

$$\int_0^{\tau_0(t)} \mathcal{R}_1(\hat{z}_r^j(r)) \, dr \to \int_0^{t} \mathcal{R}_1(z'(r)) \, dr \quad (4.16)$$

**Proof.** We split the proof in three steps.

**Step 1: compactness.** It follows from estimate (4.5) that

$$\|z_r - \hat{z}_r\|_{L^\infty(0, T; Z)}, \|z_r - z\|_{L^\infty(0, T; Z)} \leq \tau^{1/2} \|\bar{z}'_e\|_{L^2(0, T; Z)} \cdot (4.17)$$

Now, in view of (4.5) and standard compactness results, there exist a (not relabeled) sequence $(\tau^j)$ and $z \in H^1(0, T; Z)$ such that, as $j \to \infty$,

$$\hat{z}_r^j \to z \text{ in } H^1(0, T; Z), \quad \hat{z}_r^j(t) \to z(t) \text{ in } Z \text{ for all } t \in [0, T], \quad \hat{z}_r^j \to z \in C^0([0, T]; X) \quad (4.18)$$

for every Banach space $X$ such that $Z \Subset X$. Due to estimates (4.17), we conclude that, along the same sequence,

$$z_r^j(t) \to z(t) \text{ in } Z \text{ for all } t \in [0, T]. \quad (4.19)$$

**Step 2: discrete energy equality.** Arguing in the very same way as in the proof of [MRS12a, Thm. 4.10], we see that the approximate solutions $z_r^j, \hat{z}_r^j, \hat{z}_r$ fulfill the discrete energy identity

$$\int_{\hat{z}_r^j(s)}^{\tau_0(t)} \left(\mathcal{R}_1(\hat{z}_r^j)(r) + \mathcal{R}_1^*(\mathcal{I}(\hat{z}_r^j(r), z_r^j(r)))\right) \, dr + \mathcal{I}(\hat{z}_r^j(t), z_r^j(t))$$

$$= \mathcal{I}(\hat{z}_r^j(s), \hat{z}_r^j(s)) + \int_{\hat{z}_r^j(s)}^{\tau_0(t)} \mathcal{I}(\hat{z}_r^j(r), z_r^j(r)) \, dr + \int_{\hat{z}_r^j(s)}^{\tau_0(t)} \frac{1}{\tau^j(r)} F(\hat{z}_r^j(r); z_r^j(r), z_r^j(r)) \, dr \quad (4.20)$$

22
where we have used the short-hand notation \( F(t; z, w) := \mathcal{I}(t, z) - \mathcal{I}(t, w) + (D_z \mathcal{I}(t, w), w-z)_Z \). We have the following estimate

\[
|F(t; z, w)| = \left| \int_0^1 (D_z \mathcal{I}(t, w) - D_z \mathcal{I}(t, (1-\sigma)z + \sigma w), w-z)_Z \, d\sigma \right|
\leq \int_0^1 (1-\sigma)A_s(w-z, w-z) \, d\sigma + \int_0^1 \left| (D_z \mathcal{I}(t, w) - D_z \mathcal{I}(t, (1-\sigma)z + \sigma w), w-z)_Z \right| \, d\sigma
\leq \frac{1}{2} \|w-z\|_Z^2 + cs \|w-z\|_{L^p(\mathcal{D})} \|w-z\|_Z,
\]

where the last inequality follows from (2.35), and \( r \) is any fixed index in \( \left( \frac{3p}{p-2}, +\infty \right) \).

Therefore, the last term on the right-hand side of (4.20) is estimated as follows:

\[
\int_{\tau_j}^{T_{\tau_j}} \frac{1}{\tau_j^3} \left| F(\tau_j, r; z_{\tau_j}(r), \pi_{\tau_j}(r)) \right| \, dr \leq C \sup_{t \in (0, T)} \|\pi_{\tau_j}(t) - z_{\tau_j}(t)\|_Z \cdot \int_{\tau_j}^{T_{\tau_j}} \|\dot{z}_{\tau_j}(r)\|_Z \, dr. \tag{4.21}
\]

**Step 3: passage to the limit in the discrete energy inequality.** Writing (4.20) for \( s = 0 \) and any \( t \in [0, T] \), and taking into account (4.21), we find

\[
\int_0^{T_{\tau_j}} \left( R_s \dot{z}_{\tau_j}(r) + R_s^*(-D_z \mathcal{I}(\tau_j, r), \pi_{\tau_j}(r)) \right) \, dr + \mathcal{I}(\tau_j, t, \pi_{\tau_j}(t)) \\
\leq \mathcal{I}(0, z_0) + \int_0^{T_{\tau_j}} \partial_t \mathcal{I}(r, z_{\tau_j}(r)) \, dr + C \sup_{t \in (0, T)} \|\pi_{\tau_j}(t) - z_{\tau_j}(t)\|_Z \cdot \int_0^{T_{\tau_j}} \|\dot{z}_{\tau_j}(r)\|_Z \, dr. \tag{4.22}
\]

We will refer to the integral term on the left-hand side of (4.22) as \( I^1_{\tau_j} \), and to the second and third term on the right-hand side as \( I^2_{\tau_j} \) and \( I^3_{\tau_j} \), respectively. Now, we take the \( \liminf \) as \( \tau_j \to 0 \) of both sides of (4.22). Combining (4.19) with (2.38), we find that \( D_z \mathcal{I}(\tau_j, t, \pi_{\tau_j}(t)) \to D_z \mathcal{I}(t, z(t)) \) in \( Z^* \) for all \( t \in [0, T] \). Therefore, also taking into account (4.18) we conclude that \( \liminf_{\tau_j \to 0} I^1_{\tau_j} \geq \int_0^T R_s (\dot{z}(r)) + R_s^*(-D_z \mathcal{I}(r, z(r))) \, dr \). In view of (4.18) and the weak lower semicontinuity of the energy \( \mathcal{I} \), cf. (2.38), we also have that \( \liminf_{\tau_j \to 0} \mathcal{I}(\tau_j, t, \pi_{\tau_j}(t)) \geq \mathcal{I}(t, z(t)) \). Again by (4.19), (2.38) and estimate (2.26), with the Lebesgue theorem we find \( \lim_{\tau_j \to 0} I^2_{\tau_j} = \int_0^T \partial_t \mathcal{I}(r, z(r)) \, dr \). Finally,

\[
\lim_{\tau_j \to 0} I^3_{\tau_j} \leq C \lim_{\tau_j \to 0} \sup_{t \in (0, T)} \|\pi_{\tau_j} - z_{\tau_j}\|_{L^\infty(0, T; Z)} \|\dot{z}_{\tau_j}\|_{L^1(0, T; Z)} = 0, \tag{4.23}
\]

in view of the second estimate in (4.17), combined with (4.5). From the above arguments, we deduce that the limit function \( z \in H^1(0, T; Z) \) fulfills the energy inequality (3.8). In view of Proposition 3.2, we conclude that \( z \) is a solution to the Cauchy problem (3.1)-(3.2). Finally, in order to obtain (4.16), we pass to the limit in the energy identity (4.20). Observe that, thanks to (4.23), the remainder term on the right-hand side of (4.20) (viz., the third summand) converges to zero as \( \tau_j \to 0 \). Therefore, in view of the above discussion we obtain the following chain of inequalities

\[
\int_0^T (R_s (\dot{z}(r)) + R_s^*(-D_z \mathcal{I}(r, z(r)))) \, dr + \mathcal{I}(t, z(t)) \\
\leq \liminf_{\tau_j \to 0} \left( \int_0^{T_{\tau_j}} (R_s (\dot{z}_{\tau_j}(r)) + R_s^*(-D_z \mathcal{I}(\tau_j, r), \pi_{\tau_j}(r))) \, dr + \mathcal{I}(\tau_j, t, \pi_{\tau_j}(t)) \right) \\
\leq \limsup_{\tau_j \to 0} \left( \int_0^{T_{\tau_j}} (R_s (\dot{z}_{\tau_j}(r)) + R_s^*(-D_z \mathcal{I}(\tau_j, r), \pi_{\tau_j}(r))) \, dr + \mathcal{I}(\tau_j, t, \pi_{\tau_j}(t)) \right) \\
\leq \mathcal{I}(0, z_0) + \int_0^T \partial_t \mathcal{I}(r, z(r)) \, dr. \tag{4.24}
\]
Applying the chain rule (3.9) for the functional I, and arguing as described in Proposition 3.2, it follows that all inequalities in (4.24) in fact are equalities. From this, (4.16) ensues, see the similar arguments in the proof of [RMS08, Thm. 3.5], and [MRS12b, Thm. 4.4] for more details.

**Remark 4.4** (Proof of the energy inequality under the condition $z_0 \in Z$). As we have already mentioned in Remark 3.5 if we just assume $z_0 \in Z$ for the initial datum, taking the limit as $\tau \to 0$ of the time-discrete approximation, we are only able to deduce that there exists a limit curve $z \in L^\infty(0,T;Z) \cap H^1(0,T;L^2(\Omega))$ fulfilling the energy inequality (3.8), without concluding that $z$ is a solution to the Cauchy problem (3.1)–(3.2). In this connection, let us also mention that we cannot prove (3.8) simply by passing to the limit in the energy inequality (4.22). Indeed, under the sole condition $z_0 \in Z$ we are not able to obtain the crucial $H^1(0,T;Z)$-estimate (4.5) for $\dot{z}_\tau$, which guarantees that the remainder term on the right-hand side of (4.22) converges to zero, cf. (4.23).

A possible way to obtain the energy inequality (3.8) for $z$, is to pass to the limit in an *enhanced* approximate energy inequality for the interpolants of the discrete solutions, which has no remainder term on the right-hand side. Such an inequality was proved for (the time-discrete approximation of) abstract doubly nonlinear evolution equations in [MRS12b]. It involves a kind of *variational* interpolation of the discrete solutions $(z_{\tau_0})_{0 \leq k \leq N}$, i.e. the so-called *De Giorgi interpolant*, see also [Amb95, AGS08, RS06].

**Proposition 4.5.** In addition to (2.1), (2.8)–(2.10), and (2.16), suppose that
\begin{equation}
\text{the space dimension is } d = 2, \text{ hence } s = 1 \text{ and } A_s \text{ is the Laplace operator,}
\end{equation}
and the nonlinearities $f$ and $g$ have the following property
\begin{equation}
f(0) \leq f(z), \quad g(0) \leq g(z) \quad \text{for all } z \leq 0.
\end{equation}
Suppose moreover that the initial datum $z_0$ fulfills (3.10) and that
\begin{equation}
z_0(x) \in [0,1] \quad \text{for a.a. } x \in \Omega.
\end{equation}
Then, every viscous solution $z$ constructed via time-discretization also fulfills
\begin{equation}
z(t,x) \in [0,1] \quad \text{for a.a. } x \in \Omega, \text{ for all } t \in [0,T].
\end{equation}

**Proof.** Indeed, we shall prove that, starting from $z_0$ which fulfills (4.27), all solutions of the time-incremental minimization problem fulfill
\begin{equation}
z\tau_k(x) \in [0,1] \quad \text{for a.a. } x \in \Omega \quad \text{for all } k = 1, \ldots, N,
\end{equation}
and then deduce (4.28) by passing to the limit as $\tau \to 0$ in the time-discretization scheme, relying on convergences (4.18), cf. the proof of Theorem 4.3. We shall prove (4.29) by induction on the index $k$, namely we are going to show that, $z\tau_k(x) \in [0,1]$ for a.a. $x \in \Omega$ implies that $z\tau_{k+1}(x) \in [0,1]$ for a.a. $x \in \Omega$.

Indeed, on the one hand, from $R_1((z_{\tau_{k+1}} - z_{\tau_k})/\tau_k) < +\infty$ we gather that $z_{\tau_{k+1}}(x) \leq z_{\tau_k}(x) \leq 1$ for almost all $x \in \Omega$. On the other hand, it follows from (4.1) (choosing $z = (z_{\tau_{k+1}})^+$), that
\begin{align}
R_1 \left( z_{\tau_{k+1}}(x) - z_k^{\tau}(x) \right) + \frac{\epsilon}{2\tau_k} \int_{\Omega} \left| z_{\tau_{k+1}}(x) - z_k^{\tau}(x) \right|^2 \, dx + \frac{1}{2} \int_{\Omega} |\nabla z_{\tau_{k+1}}(x)|^2 \, dx + \int_{\Omega} f(z_{\tau_{k+1}}(x)) \, dx + L_2(t_{k+1}, z_{\tau_{k+1}}) \\
\leq R_1 \left( (z_{\tau_{k+1}})^+ - z_k^{\tau} \right) + \frac{\epsilon}{2\tau_k} \int_{\Omega} \left| (z_{\tau_{k+1}})^+ - z_k^{\tau}(x) \right|^2 \, dx + \frac{1}{2} \int_{\Omega} |\nabla (z_{\tau_{k+1}})^+(x)|^2 \, dx \\
+ \int_{\Omega} f((z_{\tau_{k+1}})^+(x)) \, dx + L_2(t_{k+1}, (z_{\tau_{k+1}})^+).
\end{align}
Now, with easy calculations one sees that

\[
\mathcal{R}_1((\hat{z}_k^+ + z_k^+) - \mathcal{R}_1(z_k^- - \hat{z}_k^-), \quad \|z_{k+1}^+ - z_k^+\|_{L^2(\Omega)} \leq \|z_{k+1}^- - z_k^-\|_{L^2(\Omega)},
\]

\[
\|\nabla z_{k+1}^+\|_{L^2(\Omega)} \leq \|\nabla z_{k+1}^-\|_{L^2(\Omega)}.
\]  (4.31)

Furthermore, it follows from assumption (4.26) on \( f \) that

\[
\int_{\Omega} f((z_{k+1})^+)(x) \, dx \leq \int_{\Omega} f(z_{k+1}^-)(x) \, dx.
\]  (4.32)

Moreover, again in view of (4.26),

\[
\mathcal{I}_2(t_{k+1}, (z_k^+)^+) \leq \int_{\Omega} g(z_{k+1}^-)W(\varepsilon(u_k^+ + u_D(t_{k+1}))) \, dx - \langle \ell(t_{k+1}), u_{k+1}^+ \rangle_U
\]

\[
\leq \int_{\Omega} g(z_{k+1}^-)W(\varepsilon(u_k^+ + u_D(t_{k+1}))) \, dx - \langle \ell(t_{k+1}), u_{k+1}^+ \rangle_U = \mathcal{I}_2(t_{k+1}, z_k^+),
\]  (4.33)

where we have used the short-hand notation \( u_{k+1} := u_{\min}(t_{k+1}, z_k^+) \). In view of (4.31)–(4.33), we conclude that \( (z_{k+1})^+ \) as well is a minimizer for (4.1). Since the latter minimum problem has a unique solution, we thus have \( z_{k+1}^+ \equiv (z_{k+1})^+ \). Therefore, \( z_{k+1}^+(x) \geq 0 \) for almost all \( x \in \Omega \). \( \square \)

**Remark 4.6.** Notice that \( f(z) = (1 - z)^2 \) from [Gia05] fulfills (2.8) and (4.26) as well. An example of \( g \) which complies with both (2.10) and (4.26) is

\[
g \in C^2(\mathbb{R}), \text{ } g \text{ non-decreasing, } \exists \gamma \in (0, 1) : g(z) = \gamma \text{ for } z \leq 0, \quad g(z) = 1 \text{ for } z \geq 1.
\]

Functions with this property are often used to model incomplete damage of elastic materials. The value \( z = 1 \) then describes the undamaged state, whereas \( z = 0 \) stands for maximal damage. The monotonicity of \( g \) reflects the fact that, with increasing damage (i.e. decreasing \( z \)), the material becomes weaker.

### 4.2 A uniform discrete BV-estimate

We now obtain an \( L^1([0, T]; \mathcal{Z}) \)-estimate for the derivatives \((z^\tau)^\tau\) (hence an estimate in \( BV([0, T]; \mathcal{Z}) \)) for \((z^\tau)^\tau\), with a constant *independent* of both parameters \( \tau \) and \( \epsilon \). Hereafter, we restrict to

\[
\text{uniform time steps } \tau = \tau^N = T/N
\]

and suppose that the parameters \( \tau, \epsilon \) satisfy \( \tau \leq 2\epsilon \). This is sufficient since we are ultimately interested in obtaining estimates for the limit \( \tau \to 0 \).

**Proposition 4.7.** Assume (2.1), (2.8)–(2.10) and (2.16). Suppose that \( z_0 \in \mathcal{Z} \) fulfills \( D_z\mathcal{I}(0, z_0) \in L^2(\Omega) \). Then, there exists a constant \( C_{44} \) such that for every \( \epsilon, \tau > 0 \) with \( \tau \leq 2\epsilon \) and the piecewise linear interpolants \((\hat{z}^\tau)^\tau\), defined via the solutions \( z^\tau_k \) of (4.1), the following estimate holds

\[
\int_0^T \|\hat{z}^\tau(t)\|_\mathcal{Z} \, dt \leq C_{44} \left( T + \sqrt{\epsilon} + \|D_z\mathcal{I}(0, z_0)\|_{L^2(\Omega)} + \int_0^T \mathcal{R}_1(\hat{z}^\tau(t)) \, dt \right).
\]  (4.34)

**Proof.** The idea is to combine a time-discrete Gronwall estimate with weights (generalizing [NSV00, Lemma 3.17]) with a suitable discrete version of the arguments in the proof of [MZ12, Lemma 3.4].

We start from (4.9), written for \( \rho = m_k \) and \( \sigma = m_{k-1} \), where \( m_k := \frac{1}{2}(t_k^- + t_k^+) \) and \( k \in \{2, \ldots, N\} \).

Adding the term \( \|\hat{z}^\tau(m_k)\|_{L^2(\Omega)} \) on both sides, we obtain

\[
\frac{\epsilon}{\tau} (\hat{z}^\tau(m_k) - \hat{z}^\tau(m_{k-1})) + (\hat{z}^\tau(m_k)) + \tau^{-1} (A_k(\pi^\tau(m_k) - \pi^\tau(m_{k-1})), \hat{z}^\tau(m_k))_\mathcal{Z} + \|\hat{z}^\tau(m_k)\|^2_{L^2(\Omega)}
\]

\[
\leq -\tau^{-1} (D_z\mathcal{I}(t_k, \pi^\tau(m_k)) - D_z\mathcal{I}(t_{k-1}, \pi^\tau(m_{k-1})), \hat{z}^\tau(m_k))_\mathcal{Z} + \|\hat{z}^\tau(m_k)\|^2_{L^2(\Omega)}.
\]  (4.35)
where $\tilde{z}$ is defined as in (2.33). The left-hand side of (4.35) can be estimated by

$$\text{l.h.s.} \geq \frac{\epsilon}{2\tau} \|\tilde{z}'_r(m_k)\|_{L^2(\Omega)} \left(\|\tilde{z}'_r(m_k)\|_{L^2(\Omega)} - \|\tilde{z}'_r(m_{k-1})\|_{L^2(\Omega)}\right) + \|\tilde{z}'_r(m_k)\|_Z^2.$$ 

In order to estimate the right-hand side, we proceed as follows. With $r, \sigma \in (2, \infty)$ and $\sigma_0 = \max\{r, \sigma\}$ as in the proof of Proposition 4.2, analogously to (4.12) we have

$$\text{r.h.s.} \leq C(\|\tilde{z}'_r(m_k)\|_{L^{2\sigma_0}(\Omega)}^2 + \|\tilde{z}'_r(m_k)\|_{L^{2\sigma_0}(\Omega)}) \leq C(\|\tilde{z}'_r(m_k)\|_{L^{2\sigma_0}(\Omega)}^2 + 1),$$

where in the last estimate we have used the Young inequality. Similar to the arguments subsequent to (4.12), by applying a Gagliardo-Nirenberg type inequality and Young’s inequality it follows that there exists a $\theta \in (0, 1)$ such that for $\rho > 0$ to be chosen later we obtain $\|\tilde{z}'_r(m_k)\|_{L^{2\rho}(\Omega)}^2 \leq C_\rho \|\tilde{z}'_r(m_k)\|_{L^2(\Omega)}^2 + \rho C \|\tilde{z}'_r(m_k)\|_Z^2$. Since by (1.3) it holds $\|\tilde{z}'_r(m_k)\|_{L^2(\Omega)} \leq \kappa^{-1} R_1(\tilde{z}'_r(m_k))$, suitably tuning the constant $\rho$ we arrive at

$$\text{r.h.s.} \leq \frac{1}{2} \|\tilde{z}'_r(m_k)\|_Z^2 + C \left(1 + \|\tilde{z}'_r(m_k)\|_{L^2(\Omega)} R_1(\tilde{z}'_r(m_k))\right).$$

Hence, estimate (4.35) yields

$$\frac{\epsilon}{2\tau} \|\tilde{z}'_r(m_k)\|_{L^2(\Omega)} \left(\|\tilde{z}'_r(m_k)\|_{L^2(\Omega)} - \|\tilde{z}'_r(m_{k-1})\|_{L^2(\Omega)}\right) + \frac{1}{2} \|\tilde{z}'_r(m_k)\|_Z^2 \leq C \left(1 + \|\tilde{z}'_r(m_k)\|_{L^2(\Omega)} R_1(\tilde{z}'_r(m_k))\right),$$

where the constant $C$ is independent of $\tau, k$ and $\epsilon$. Multiplying this inequality by $4\tau/\epsilon$ and taking into account that $\|\tilde{z}'_r(m_k)\|_Z^2 \geq \|\tilde{z}'_r(m_k)\|_{L^2(\Omega)}^2$, we arrive at

$$2 \|\tilde{z}'_r(m_k)\|_{L^2(\Omega)} \left(\|\tilde{z}'_r(m_k)\|_{L^2(\Omega)} - \|\tilde{z}'_r(m_{k-1})\|_{L^2(\Omega)}\right) + \frac{\tau}{\epsilon} \|\tilde{z}'_r(m_k)\|_Z^2 \leq \frac{4\tau C}{\epsilon} + \frac{4\tau C}{\epsilon} \|\tilde{z}'_r(m_k)\|_{L^2(\Omega)} R_1(\tilde{z}'_r(m_k)), \quad (4.36)$$

which is valid for all $2 \leq k \leq N$. We define now for $0 \leq i \leq N - 1$

$$a_i = \|\tilde{z}'_r(m_{i+1})\|_{L^2(\Omega)}, \quad b_i = (\tau/\epsilon)^\frac{1}{2} \|\tilde{z}'_r(m_{i+1})\|_Z, \quad c_i = (4\tau C/\epsilon)^\frac{1}{2}, \quad d_i = \frac{2\tau C}{\epsilon} R_1(\tilde{z}'_r(m_{i+1})), \quad \gamma = \frac{\tau}{2\epsilon}.\]

With this, (4.36) can be rewritten as

$$2a_i(a_i - a_{i-1}) + 2\gamma a_i^2 + b_i^2 \leq c_i^2 + 2a_id_i,$$

which holds for $1 \leq i \leq N - 1$. Thus, estimate (4.51) in Lemma 4.9 below implies that for all $j \leq N - 1$

$$\sum_{i=1}^j(1 + \gamma)^{2(i-j)-1}b_i^2 \leq 2(1 + \gamma)^{-2j}a_0^2 + 2 \sum_{i=1}^j(1 + \gamma)^{2(i-j)-1}c_i^2 + 4 \left(\sum_{i=1}^j(1 + \gamma)^{i-j-1}d_i\right)^2.$$

Reinserting the explicit values of $a_i$, $b_i$ and $d_i$, and using the fact that $c_i^2 = 8C\gamma$, the above inequality yields for $2 \leq n \leq N$ (with $i + 1 = k$, $n = j + 1$):

$$\frac{1}{\epsilon} \sum_{k=2}^n \tau(1 + \gamma)^{2(k-n)-1} \|\tilde{z}'_r(m_k)\|_Z^2 \leq 2(1 + \gamma)^{-2n} \|\tilde{z}'_r(m_1)\|_{L^2(\Omega)} + 16C\gamma \sum_{k=2}^n(1 + \gamma)^{2(k-n)-1} + 16C^2 \left(\sum_{k=2}^n\frac{\tau}{\epsilon}(1 + \gamma)^{k-n-1}R_1(\tilde{z}'_r(m_k))\right)^2. \quad (4.37)$$
We now calculate and estimate the second term on the right-hand side of (4.37) explicitly, using that by assumption we have $\gamma \leq 1$:

$$\gamma \sum_{k=2}^{n+1} (1 + \gamma)^{2(k-n)-1} \leq \gamma(1 + \gamma)^{-2n-1} \frac{1 - (1 + \gamma)^{2(n+1)}}{1 - (1 + \gamma)^2} \leq \frac{1}{2}(1 + \gamma) \leq 1.$$  \hspace{1cm} (4.38)

Combining (4.38) with (4.37) yields

$$\frac{1}{\epsilon} \sum_{k=2}^{n} \tau (1 + \gamma)^{2(k-n)-1} \|z'_r(m_k)\|_Z^2 \leq C \left( 1 + (1 + \gamma)^{-2n} \|z'_r(m_1)\|_{L^2(\Omega)}^2 + \sum_{k=2}^{n} \frac{\tau}{\epsilon} (1 + \gamma)^{k-n-1} R_1(z'_r(m_k)) \right)$$  \hspace{1cm} (4.39)

which is the discrete counterpart of estimate (3.23) in [MZ12].

We now proceed following the arguments in the proof of [MZ12, Lemma 3.4], translating them in the present time-discrete setting. Let us stress once again that, hereafter, the generic constant $C > 0$ shall be independent of $\tau$ and $\epsilon$. We start by observing that, by Hölder inequality,

$$\frac{1}{\epsilon} \sum_{k=2}^{n} \tau (1 + \gamma)^{2(k-n)-1} \|z'_r(m_k)\|_Z \leq \left( \sum_{k=2}^{n} \frac{\tau}{\epsilon} (1 + \gamma)^{2(k-n)-1} \right)^{\frac{1}{2}} \left( \sum_{k=2}^{n} \frac{\tau}{\epsilon} (1 + \gamma)^{2(k-n)-1} \|z'_r(m_k)\|_Z^2 \right)^{\frac{1}{2}}.$$  \hspace{1cm} (4.40)

Recalling that $\frac{\tau}{\epsilon} = 2\gamma \leq 2$ we find with (4.38) that the first factor on the right-hand side is bounded by $\sqrt{2}$. Hence, from (4.40) and (4.39) we deduce

$$\frac{1}{\epsilon} \sum_{k=2}^{n} \tau (1 + \gamma)^{2(k-n)-1} \|z'_r(m_k)\|_Z \leq C \left( 1 + (1 + \gamma)^{-n} \|z'_r(m_1)\|_{L^2(\Omega)} + \sum_{k=2}^{n} \frac{\tau}{\epsilon} (1 + \gamma)^{k-n-1} R_1(z'_r(m_k)) \right).$$  \hspace{1cm} (4.41)

Now we multiply both sides of (4.41) by $\tau$ and sum over $n = 2, \ldots, N$:

$$\frac{1}{\epsilon} \sum_{n=2}^{N} \tau \sum_{k=2}^{n} \tau (1 + \gamma)^{2(k-n)-1} \|z'_r(m_k)\|_Z \leq C \sum_{n=2}^{N} \tau \left( 1 + (1 + \gamma)^{-n} \|z'_r(m_1)\|_{L^2(\Omega)} + \sum_{k=2}^{n} \frac{\tau}{\epsilon} (1 + \gamma)^{k-n-1} R_1(z'_r(m_k)) \right).$$  \hspace{1cm} (4.42)

We discuss the different terms on the left-hand and on the right-hand side of (4.42) separately. Now, we introduce for every $k, n = 2, \ldots, N$ the coefficient $e_k^n$ defined by $1$ if $k \leq n$ and $0$ if $k > n$. This coefficient will be used below to change the order of the sums. Starting with the left-hand side of (4.42), we have

$$\frac{1}{\epsilon} \sum_{n=2}^{N} \tau \sum_{k=2}^{n} \tau (1 + \gamma)^{2(k-n)-1} \|z'_r(m_k)\|_Z = \frac{1}{\epsilon} \sum_{n=2}^{N} \tau \sum_{k=2}^{n} \tau e_k^n (1 + \gamma)^{2(k-n)-1} \|z'_r(m_k)\|_Z$$

$$= \sum_{k=2}^{N} \tau \|z'_r(m_k)\|_Z \sum_{n=k}^{N} \frac{\tau}{\epsilon} (1 + \gamma)^{2(k-n)-1}$$

$$= \frac{2}{2 + \gamma} \sum_{k=2}^{N} \tau \|z'_r(m_k)\|_Z \left( 1 - (1 + \gamma)^{2(N-k-2)} \right).$$

27
Passing to the right-hand side of (4.42), using again the definition of $\gamma$ we find
\[
\sum_{n=2}^{N} \tau (1 + \gamma)^{-n} \| \hat{z}'_\tau (m_1) \|_{L^2(\Omega)} \leq 4 \epsilon \| \hat{z}'_\tau (m_1) \|_{L^2(\Omega)} .
\] (4.44)

Next we discuss the term
\[
\sum_{n=2}^{N} \tau \sum_{k=2}^{n} \frac{\tau (1 + \gamma)^{k-n-1} R_1(z'_\tau (m_k))}{\epsilon} = \sum_{k=2}^{N} \tau R_1(z'_\tau (m_k)) \sum_{n=k}^{N} \frac{\tau (1 + \gamma)^{k-n-1}}{\epsilon} \leq 2 \sum_{k=2}^{N} \tau R_1(z'_\tau (m_k)),
\] (4.45)

where the last inequality follows from calculations analogous to (4.43). Combining (4.42) with (4.43)–(4.45), and recalling that $\tau = \frac{T}{n}$ so that $\sum_{n=2}^{N} \tau \leq T$, we get
\[
\sum_{k=2}^{N} \tau \| z'_\tau (m_k) \|_{Z} \left(1 - (1 + \gamma)^{2(k-N)-2}\right) \leq C \left(T + \epsilon \| z'_\tau (m_1) \|_{L^2(\Omega)} + \sum_{k=2}^{N} \tau R_1(z'_\tau (m_k)) \right).
\]
that is
\[
\sum_{k=2}^{N} \tau \| z'_\tau (m_k) \|_{Z} \leq C \left(T + \epsilon \| z'_\tau (m_1) \|_{L^2(\Omega)} + \sum_{k=2}^{N} \tau R_1(z'_\tau (m_k)) \right) + \sum_{k=2}^{N} \tau (1 + \gamma)^{2(k-N)-2} \| z'_\tau (m_k) \|_{Z}.
\] (4.46)

Using (4.41) to estimate the last term in (4.46), we arrive at
\[
\sum_{k=2}^{N} \tau \| z'_\tau (m_k) \|_{Z} \leq C \left(T + \epsilon \| z'_\tau (m_1) \|_{L^2(\Omega)} + \sum_{k=2}^{N} \tau R_1(z'_\tau (m_k)) \right).
\] (4.47)

Taking into account (4.6) together with $\tau \leq 2 \epsilon$, we finally obtain (4.34).

Combining estimate (4.34) with (4.16) it follows that

**Corollary 4.8.** Assume (2.1), (2.8), (2.10) and (2.16). Suppose that $z_0 \in Z$ and that $D_2 I(0, z_0) \in L^2(\Omega)$. For $\epsilon \in (0, \epsilon_0]$ let $(z_\epsilon)_\tau \in H^1(0, T; Z)$ be a family of solutions to the Cauchy problem for (3.1), which are limits of sequences $(z_{\epsilon, \tau})_{\tau \to 0}$ of solutions to (4.1) (as in the statement of Theorem 4.3).

Then there exist constants $C_{15}, C_{16} > 0$ such that for all $\epsilon > 0$ it holds
\[
\int_0^T \| z'_\epsilon(t) \|_Z \ dt \leq C_{15} \| D_2 I(0, z_0) \|_{L^2(\Omega)} + C_{16} \int_0^T (1 + R_1(z'_\epsilon(t))) \ dt.
\] (4.48)

Estimate (3.12) then follows from inequality (4.48), taking into account that from the energy identity (3.7) it can be deduced that $\sup_{\epsilon > 0} \int_0^T R_1(z'_\epsilon(t)) \ dt \leq C$.

In the proof of Proposition 4.7 we used the following time-discrete Gronwall-type estimate with weights.

**Lemma 4.9.** Let $\{a_k\}_{k=0}^{N}$ and $\{b_k, c_k, d_k\}_{k=1}^{N}$ be nonnegative numbers and $\gamma \geq 0$. Assume that for $1 \leq k \leq N$ it holds
\[
2a_k(a_k - a_{k-1}) + 2\gamma a_k^2 + b_k^2 \leq c_k^2 + 2a_k d_k.
\] (4.49)
Then the following estimates are valid for all \( n \geq 1 \):

\[
a_n \leq \left( (1 + \gamma)^{-2n}a_0^2 + \sum_{k=1}^{n} (1 + \gamma)^{2(k-n)-1}c_k^2 \right)^{\frac{1}{2}} + \sum_{k=1}^{n} (1 + \gamma)^{k-n-1}d_k, \tag{4.50}
\]

\[
\left( \sum_{k=1}^{n} (1 + \gamma)^{2(k-n)-1}b_k^2 \right)^{\frac{1}{2}} \leq \left( (1 + \gamma)^{-2n}a_0^2 + \sum_{k=1}^{n} (1 + \gamma)^{2(k-n)-1}c_k^2 \right)^{\frac{1}{2}} + \sqrt{2} \sum_{k=1}^{n} (1 + \gamma)^{k-n-1}d_k. \tag{4.51}
\]

**Remark 4.10.** If \( \gamma = 0 \), then Lemma 4.9 exactly reproduces [NSV00, Lemma 3.17]. Hence, our proof follows closely the steps in [NSV00], introducing the weight \((1 + \gamma)^n\) in a suitable way.

**Proof.** We set \( a_0 = R_0 \) and define for \( 1 \leq n \leq N \) the quantities

\[
R_n = \xi_n + \delta_n, \quad \delta_n = \sum_{k=1}^{n} (1 + \gamma)^{k-n-1}d_k, \tag{4.52}
\]

\[
\xi_n = \left( (1 + \gamma)^{-2n}a_0^2 + \sum_{k=1}^{n} (1 + \gamma)^{2(k-n)-1}c_k^2 \right)^{\frac{1}{2}}. \tag{4.53}
\]

As in [NSV00], we first prove the inequality \( a_n \leq R_n \) for all \( 1 \leq n \leq N \), which then gives (4.50). Since \( b_n \geq 0 \), from (4.49) we find that

\[
(1 + \gamma)a_n^2 - (a_{n-1} + d_n)a_n \leq \frac{1}{2}c_n^2.
\]

Hence, investigating the roots of \( a_n \) in the quadratic inequality, we find since \( a_n \geq 0 \)

\[
2(1 + \gamma)a_n \leq a_{n-1} + d_n + ((a_{n-1} + d_n)^2 + 2(1 + \gamma)c_n^2)^{\frac{1}{2}}. \tag{4.54}
\]

Observe that \( (1 + \gamma)\delta_n = \delta_{n-1} + d_n \) and that \( (1 + \gamma)\xi_n \geq \xi_{n-1} \). Therefore, from the definition of \( R_n \) it follows that

\[
(1 + \gamma)R_n^2 - (R_{n-1} + d_n)R_n = R_n \left( (1 + \gamma)\xi_n + (1 + \gamma)\delta_n - \xi_{n-1} - \delta_{n-1} - d_n \right)
\geq \xi_n (1 + \gamma)\xi_n - \xi_{n-1} \n
\]

Using Young’s inequality with \( \xi_n \xi_{n-1} \leq \frac{1}{2}((1 + \gamma)\xi_n^2 + (1 + \gamma)^{-1}\xi_{n-1}^2) \) and taking into account the definition of \( \xi_n \), we conclude that

\[
\xi_n ((1 + \gamma)\xi_n - \xi_{n-1}) \geq \frac{1}{2} ((1 + \gamma)\xi_n^2 - (1 + \gamma)^{-1}\xi_{n-1}^2) = \frac{c_n^2}{2}.
\]

Hence, we have shown that

\[
(1 + \gamma)R_n^2 - (R_{n-1} + d_n)R_n \geq \frac{1}{2}c_n^2.
\]

In the same way as for \( a_n \) (cf. (4.54)), we deduce the estimate

\[
2(1 + \gamma)R_n \geq R_{n-1} + d_n + ((R_{n-1} + d_n)^2 + 2(1 + \gamma)c_n^2)^{\frac{1}{2}}. \tag{4.55}
\]

Since \( a_0 = R_0 \), by induction from (4.54) and (4.55) we have \( a_n \leq R_n \) for every \( n \leq N \), whence (4.50).

We now prove (4.51). Let \( 1 \leq n \leq N \). From (4.49), applying the Young inequality to the term \( 2a_k a_{k-1} \) and taking into account that \( a_k \leq R_k \), we find for \( 1 \leq k \leq n \)

\[
b_k^2 \leq c_k^2 + 2R_k d_k + (1 + \gamma)^{-1}a_{k-1}^2 - (1 + \gamma)a_k^2.
\]

29
Multiplying this inequality with \((1 + \gamma)^{2(k-n)-1}\), using that \((1 + \gamma)^{k-n} R_k \leq R_n\) and summing up we obtain

\[
\sum_{k=1}^{n} (1 + \gamma)^{2(k-n)-1} b_k^2 \leq \sum_{k=1}^{n} (1 + \gamma)^{2(k-n)-1} c_k^2 + 2 R_n \sum_{k=1}^{n} (1 + \gamma)^{k-n-1} d_k
\]

\[
+ \sum_{k=1}^{n} (1 + \gamma)^{2(k-n)-2} a_{k-1}^2 - \sum_{k=1}^{n} (1 + \gamma)^{2(k-n)} a_k^2.
\]

(4.56)

Observe that the last two terms add up to \((1 + \gamma)^{-2n} a_0^2 - a_n^2\). Thus, we finally arrive at

\[
\sum_{k=1}^{n} (1 + \gamma)^{2(k-n)-1} b_k^2 \leq \xi_n^2 + 2 R_n \delta_n \leq \left(\xi_n + \sqrt{2} \delta_n\right)^2,
\]

whence (4.51).

\[\square\]

5 Existence of parameterized solutions

Throughout this section, we shall work with a family \(\{z_\epsilon\}_\epsilon \subset H^1(0,T;Z)\) of solutions to the \(\epsilon\)-viscous Cauchy problem (3.1)–(3.2), for which the \(L^1\)-estimate

\[
\sup_{\epsilon > 0} \int_{0}^{T} \|z'_\epsilon(t)\|_Z \, dt \leq C < \infty \tag{5.1}
\]

is valid. The existence of such a family is ensured by Theorem 3.3, under condition (3.10) on the initial datum \(z_0 \in Z\).

5.1 The vanishing viscosity analysis

For every \(\epsilon > 0\), we consider the graph \(\text{Graph}(z_\epsilon) := \{(t, z_\epsilon(t)) ; t \in [0,T]\} \subset [0,T] \times Z\) and its \(Z\)-arclength parameterization

\[
s_\epsilon(t) = t + \int_{0}^{t} \|z'_\epsilon(r)\|_Z \, dr.
\]

(5.2)

For \(S_\epsilon = s_\epsilon(T)\) we introduce the functions \(\hat{t}_\epsilon : [0,S_\epsilon] \to [0,T]\) and \(\hat{z}_\epsilon : [0,S_\epsilon] \to Z\)

\[
\hat{t}_\epsilon(s) := s^{-1}_\epsilon(s), \quad \hat{z}_\epsilon(s) := z_\epsilon(\hat{t}_\epsilon(s)) \tag{5.3}
\]

and study the limiting behavior as \(\epsilon \to 0\) of the parameterized trajectories \(\{(\hat{t}_\epsilon(s), \hat{z}_\epsilon(s)) ; s \in [0,S_\epsilon]\}\), which fulfill the normalization condition

\[
\hat{t}'_\epsilon(s) + \|\hat{z}'_\epsilon(s)\|_Z = 1 \quad \text{for a.a.} \ s \in (0,S_\epsilon).
\]

(5.4)

Observe that, in view of estimate (5.1), there holds \(\sup_{\epsilon > 0} S_\epsilon < +\infty\). Therefore, up to a subsequence \(S_\epsilon \to S\) as \(\epsilon \to 0\), with \(S \geq T\) (the latter inequality follows from the fact that \(s_\epsilon(t) \geq t\)). With no loss of generality, we may consider the parameterized trajectories to be defined on the fixed time interval \([0,S]\).

For this passage to the limit, following [MRS09, MRS12a] we adopt an energetic viewpoint, i.e. we take the limit of the energy identity fulfilled by the parameterized trajectories \(\{(\hat{t}_\epsilon(s), \hat{z}_\epsilon(s)) ; s \in [0,S]\}\). Setting

\[
d_2(\xi, \partial R_1(0)) := \min_{\mu \in \partial R_1(0)} \sqrt{2 \mathcal{H}_2(\xi - \mu)}
\]

30
the energy identity (3.11) written for the pair \((\hat{t}_\varepsilon, \hat{z}_\varepsilon)\) on any time interval \((\sigma_1, \sigma_2) \subset [0, S]\) reads

\[
\int_{\sigma_1}^{\sigma_2} \left( R_1(\hat{z}_\varepsilon(s)) + \frac{\varepsilon}{2t_\varepsilon(s)} \|\hat{z}_\varepsilon(s)\|^2_{L^2(\Omega)} + \frac{t_\varepsilon(s)}{2\varepsilon} d_2^2(-D_2I(\hat{t}_\varepsilon(s), \hat{z}_\varepsilon(s)), \partial R_1(0)) \right) ds + I(\hat{t}_\varepsilon(\sigma_2), \hat{z}_\varepsilon(\sigma_2))
\]

\[
= I(\hat{t}_\varepsilon(\sigma_1), \hat{z}_\varepsilon(\sigma_1)) + \int_{\sigma_1}^{\sigma_2} \partial_t I(\hat{t}_\varepsilon(s), \hat{z}_\varepsilon(s)) t_\varepsilon(s) ds.
\]

The above identity can be also reformulated by means of the functional (cf. [MRS09, Sec. 3.2])

\[
\mathcal{M}_\varepsilon : (0, +\infty) \times L^2(\Omega) \times [0, +\infty) \to [0, +\infty], \quad \mathcal{M}_\varepsilon(\alpha, v, \zeta) := R_1(v) + \frac{\varepsilon}{2\alpha} \|v\|^2_{L^2(\Omega)} + \frac{\alpha}{2\varepsilon} \zeta^2,
\]

whence

\[
\int_{\sigma_1}^{\sigma_2} \mathcal{M}_\varepsilon(\hat{t}_\varepsilon(s), \hat{z}_\varepsilon(s), t_\varepsilon(s)) ds + I(\hat{t}_\varepsilon(\sigma_2), \hat{z}_\varepsilon(\sigma_2))
\]

\[
= I(\hat{t}_\varepsilon(\sigma_1), \hat{z}_\varepsilon(\sigma_1)) + \int_{\sigma_1}^{\sigma_2} \partial_t I(\hat{t}_\varepsilon(s), \hat{z}_\varepsilon(s)) \hat{t}_\varepsilon(s) ds.
\]

For the passage to the limit as \(\varepsilon \to 0\) in (5.6), we shall rely on the following \(\Gamma\)-convergence/lower semicontinuity result, which was proved in a finite-dimensional setting in [MRS09] (cf. Lemma 3.1 therein).

**Lemma 5.1.** Extend the functional \(\mathcal{M}_\varepsilon\) (5.5) to \([0, +\infty) \times L^2(\Omega) \times [0, +\infty)\) via

\[
\mathcal{M}_\varepsilon(0, v, \zeta) := \begin{cases} 0 & \text{for } v = 0 \text{ and } \zeta \in [0, +\infty), \\ +\infty & \text{for } v \in L^2(\Omega) \setminus \{0\} \text{ and } \zeta \in [0, +\infty). \end{cases}
\]

Define \(\mathcal{M}_0 : [0, +\infty) \times L^2(\Omega) \times [0, +\infty) \to [0, +\infty]\) by

\[
\mathcal{M}_0(\alpha, v, \zeta) := \begin{cases} R_1(v) + \zeta \|v\|_{L^2(\Omega)} & \text{if } \alpha = 0, \\ R_1(v) + I_0(\zeta) & \text{if } \alpha > 0, \end{cases}
\]

where \(I_0\) denotes the indicator function of the singleton \([0, 0]\). Then,

(A) \(\mathcal{M}_\varepsilon\) \(\Gamma\)-converges to \(\mathcal{M}_0\) on \([0, +\infty) \times L^2(\Omega) \times [0, +\infty)\) w.r. to the strong-weak-strong topology, viz.

\(\Gamma\)-liminf estimate:

\[
(\alpha_\varepsilon, \zeta_\varepsilon) \to (\alpha, \zeta) \text{ and } v_\varepsilon \to v \text{ in } L^2(\Omega) \implies \mathcal{M}_0(\alpha, v, \zeta) \leq \liminf_{\varepsilon \to 0} \mathcal{M}_\varepsilon(\alpha_\varepsilon, v_\varepsilon, \zeta_\varepsilon),
\]

\(\Gamma\)-limsup estimate:

\[
\forall (\alpha, v, \zeta) \exists (\alpha_\varepsilon, v_\varepsilon, \zeta_\varepsilon)_{\varepsilon > 0} : (\alpha_\varepsilon, \zeta_\varepsilon) \to (\alpha, \zeta), \quad v_\varepsilon \to v \text{ in } L^2(\Omega) \quad \text{and} \quad \mathcal{M}_0(\alpha, v, \zeta) \geq \limsup_{\varepsilon \to 0} \mathcal{M}_\varepsilon(\alpha_\varepsilon, v_\varepsilon, \zeta_\varepsilon).
\]

(B) If \(\alpha_\varepsilon \to \bar{\alpha} \in L^1(a, b), \quad v_\varepsilon \to \bar{v} \in L^1(a, b; L^2(\Omega)), \quad \text{and} \liminf_{\varepsilon \to 0} \zeta_\varepsilon(s) \geq \zeta(s) \text{ for a.a. } s \in (a, b), \) then

\[
\int_a^b \mathcal{M}_0(\bar{\alpha}(s), \bar{v}(s), \bar{\zeta}(s)) ds \leq \liminf_{\varepsilon \to 0} \int_a^b \mathcal{M}_\varepsilon(\alpha_\varepsilon(s), v_\varepsilon(s), \zeta_\varepsilon(s)) ds.
\]

The proof can be developed arguing in the same way as in the proof of [MRS09, Lemma 3.1], up to replacing the usage of Ioffe’s theorem [Iof77] with its infinite-dimensional version, see e.g. [Val90, Thm. 21]. Moving from this result, and following [MRS09, Def. 3.2], [MRS12a, Def. 5.2], we give the ensuing
Definition 5.2. A pair \((\hat{t}, \hat{z}) \in C^0_{\text{lip}}([0,S]; [0,T] \times \mathcal{Z})\) is a \(\mathcal{Z}\)-parameterized solution of (1.6), if it satisfies the energy identity for all \(0 \leq \sigma_1 \leq \sigma_2 \leq S\)

\[
\int_{\sigma_1}^{\sigma_2} M_0(\dot{\rho}(s), \dot{z}(s), d\mathcal{H}(\hat{t}(s), \hat{z}(s), \partial \mathcal{R}_1(0))) \, ds + \mathcal{I}(\hat{t}(\sigma_2), \hat{z}(\sigma_2)) = \mathcal{I}(\hat{t}(\sigma_1), \hat{z}(\sigma_1)) + \int_{\sigma_1}^{\sigma_2} \partial_s \mathcal{I}(\hat{t}(s), \hat{z}(s)) \dot{\rho}(s) \, ds.
\]  

(5.9)

We say that a \(\mathcal{Z}\)-parameterized solution \((\hat{t}, \hat{z}) \in C^0_{\text{lip}}([0,S]; [0,T] \times \mathcal{Z})\) is non-degenerate if it fulfills

\[
\dot{\rho}(s) + \|\dot{z}'(s)\|_\mathcal{Z} > 0 \quad \text{for a.a. } s \in (0,S).
\]  

(5.10)

We are now in the position of stating the main result of this section.

Theorem 5.3. Let \(s = d/2\). Assume (2.1), (2.8)–(2.10), and (2.16). Let \((z_\epsilon) \subset H^1(0,T; \mathcal{Z})\) be a family of solutions to the \(\epsilon\)-viscous problem (3.1)–(3.2), for which estimate (5.1) is valid, and let \((\hat{t}_\epsilon, \hat{z}_\epsilon)_{\epsilon > 0} \subset C^0_{\text{lip}}([0,S]; [0,T] \times \mathcal{Z})\) be defined by (5.3).

Then, for every sequence \(\epsilon_n \searrow 0\) there exist a pair \((\hat{t}, \hat{z}) \in C^0_{\text{lip}}([0,S]; [0,T] \times \mathcal{Z})\) and a (not-relabeled) subsequence such that

\[
(\hat{t}_{\epsilon_n}; \hat{z}_{\epsilon_n}) \rightarrow (\hat{t}, \hat{z}) \text{ in } W^{1,\infty}(0,S; [0,T] \times \mathcal{Z}),
\]

\[
\hat{t}_{\epsilon_n} \rightarrow \hat{t} \text{ in } C^0([0,S]; [0,T]), \quad \hat{z}_{\epsilon_n}(s) \rightarrow \hat{z}(s) \text{ in } \mathcal{Z} \text{ for all } s \in [0,S],
\]  

(5.11)

and \((\hat{t}, \hat{z})\) is a \(\mathcal{Z}\)-parameterized solution of (1.6), fulfilling

\[
\dot{\rho}(s) + \|\dot{z}'(s)\|_\mathcal{Z} \leq 1 \quad \text{for a.a. } s \in (0,S).
\]  

(5.12)

Remark 5.4. At the moment, it remains an open problem to prove that, the limiting \(\mathcal{Z}\)-parameterized solution in Thm. 5.3 is also non-degenerate. Without going into details, we may mention that, in some sense, this is due to the gap between condition (5.10), which involves the \(\mathcal{H}\)-norm of \(\dot{z}'\), and our energetic method for taking the vanishing viscosity limit of (3.1). The mismatch occurs because, neither the viscous energy identity (5.6), nor its limit (5.9) contain information on the term \(\|\dot{z}'\|_\mathcal{Z}\).

These considerations also suggest that, in order to obtain non-degenerate parameterized solutions, it could be necessary to implement on this vanishing viscosity limit the alternative reparameterization techniques which we will discuss in Section 5.3. We plan to address this issue in a future paper.

Remark 5.5. By reparameterizing degenerate \(\mathcal{Z}\)-parameterized solutions, non-degenerate \(\mathcal{Z}\)-parameterized solutions can be obtained: Let \((\hat{t}, \hat{z}) \in W^{1,\infty}(0,S; \mathbb{R}) \times W^{1,\infty}(0,S; \mathcal{Z})\) be a \(\mathcal{Z}\)-parameterized solution with \(\dot{\rho}(\rho) + \|\dot{z}'(\rho)\|_\mathcal{Z} \leq 1\) for a.a. \(\rho \in (0,S)\). Define \(m(\rho) := \int_0^\rho \dot{\rho}(\sigma) + \|\dot{z}'(\sigma)\|_\mathcal{Z} \, d\sigma\), \(r(\mu) := \inf \{\rho \geq 0; m(\rho) = \mu\}\) and \(\hat{t}(\mu) := \hat{t}(r(\mu)), \hat{z}(\mu) = \hat{z}(r(\mu))\). Clearly, \(m\) is monotone and Lipschitz while \(r\) is monotone and belongs to \(\text{BV}([0,R])\) with \(R := r(m(S))\). Moreover, it holds \(m(r(\mu)) = \mu\) and for every \(\mu \in J(r)\) (where \(J(r)\) denotes the jump set of the BV-function \(r\)) we have \(m(r(\mu)) = m(r(\mu^+))\).

Hence, with the chain rule in [AFP00, Theorem 3.96] it follows that

\[
d\mu = Dm(r(\cdot)) \, d\bar{r} + \sum_{\mu \in J(r)} (m(r(\mu^+)) - m(r(\mu^-))) d\mu = m'(r(\cdot)) d\bar{r}.
\]  

(5.13)

Here, \(\bar{r}\) denotes the diffuse part of the distributional derivative \(r\). The Lipschitz continuity of \(\hat{t}\) and \(\hat{z}\) now is an immediate consequence of the above calculations. Indeed, let \(0 \leq \mu_1 \leq \mu_2 \leq R\). Then

\[
0 \leq \hat{t}(\mu_2) - \hat{t}(\mu_1) = \int_{\mu_1}^{\mu_2} \hat{t}'(r(\mu)) \, d\bar{r}(\mu) = \int_{\mu_1}^{\mu_2} \left( m'(r(\mu)) - \|\dot{z}'(r(\mu))\|_\mathcal{Z} \right) \, d\bar{r}(\mu)
\]

\[
= \int_{\mu_1}^{\mu_2} d\mu - \int_{\mu_1}^{\mu_2} \|\dot{z}'(r(\mu))\|_\mathcal{Z} \, d\bar{r}(\mu) \leq \mu_2 - \mu_1,
\]
where the second equality is due to the definition of \( m \) and the third one follows from (5.13). The last inequality is due to the monotonicity of \( r \). Similarly we show that \( \tilde{z} \) is Lipschitz continuous. Hence, the pair \((\tilde{t}, \tilde{z})\) belongs to \( W^{1,\infty}(0, R; \mathbb{R}) \times W^{1,\infty}(0, R; \mathcal{Z}) \) and satisfies \( \tilde{r}(\mu) + \| \tilde{z}'(\mu) \|_2 = 1 \) for a.a. \( \mu \in (0, R) \). Finally, it is easy to check that \((\tilde{t}, \tilde{z})\) satisfies the energy identity (5.9), whence \((\tilde{t}, \tilde{z})\) is a non-degenerate \( \mathcal{Z} \)-parameterized solution of (1.6).

The proof of Theorem 5.3 is based on the following result, which is the “parameterized counterpart” to Proposition 3.2. Indeed, it provides an equivalent formulation of (5.9). The reader is referred to [MRS12a, Prop. 5.3] for further characterizations of parameterized solutions.

**Lemma 5.6.** Let \( s = d/2 \). Assume (2.1), (2.8)–(2.10), and (2.16). Then, a pair \((\tilde{t}, \tilde{z}) \in C^0_{\text{lip}}([0, S]; [0, T] \times \mathcal{Z})\) is a \( \mathcal{Z} \)-parameterized solution of (1.6) if and only if it satisfies for all \( 0 \leq \sigma \leq S \) the energy inequality

\[
\int_0^\sigma \mathcal{M}_0(\tilde{r}'(s), \tilde{z}'(s), d_2(-D_2\mathcal{I}(\tilde{t}(s), \tilde{z}(s), \partial\mathcal{R}_1(0)))) \, ds + \mathcal{I}(\tilde{t}(\sigma), \tilde{z}(\sigma)) \\ \leq \mathcal{I}(\tilde{t}(0), \tilde{z}(0)) + \int_0^\sigma \partial_s \mathcal{I}(\tilde{t}(s), \tilde{z}(s)) \tilde{r}'(s) \, ds.
\]

(5.14)

**Proof.** Like in the proof of Proposition 3.2, we observe that, due to the smoothness of the energy functional \( \mathcal{I} \) (cf. Corollary 2.9), any pair \((\tilde{t}, \tilde{z}) \in C^0_{\text{lip}}([0, S]; [0, T] \times \mathcal{Z})\) fulfills the “parameterized chain rule” identity

\[
\frac{d}{ds} \mathcal{I}(\tilde{t}(s), \tilde{z}(s)) = \partial_s \mathcal{I}(\tilde{t}(s), \tilde{z}(s)) \tilde{r}'(s) + \langle D_2\mathcal{I}(\tilde{t}(s), \tilde{z}(s)), \tilde{z}'(s) \rangle_{\mathcal{Z}} \quad \text{for a.a. } s \in (0, S).
\]

(5.15)

Now, let \( \mu(s) \in \partial\mathcal{R}_1(0) \) satisfy \( \| -D_2\mathcal{I}(\tilde{t}(s), \mu(s)) \|_{L^2(\Omega)} = d_2(-D_2\mathcal{I}(\tilde{t}(s), \tilde{z}(s), \partial\mathcal{R}_1(0))) \) for almost all \( s \in (0, S) \) (cf. Lemma 3.1). Then, there holds

\[
- \frac{d}{ds} \mathcal{I}(\tilde{t}(s), \tilde{z}(s)) + \partial_s \mathcal{I}(\tilde{t}(s), \tilde{z}(s)) \tilde{r}'(s) = \langle -D_2\mathcal{I}(\tilde{t}(s), \tilde{z}(s)) - \mu(s), \tilde{z}'(s) \rangle_{L^2(\Omega)} + \langle \mu(s), \tilde{z}'(s) \rangle_{\mathcal{Z}} \leq d_2(-D_2\mathcal{I}(\tilde{t}(s), \tilde{z}(s), \partial\mathcal{R}_1(0))) \| \tilde{z}'(s) \|_{L^2(\Omega)} + \mathcal{R}_1(\tilde{z}'(s)),
\]

(5.16)

where the latter inequality follows from the definition (1.4) of \( \partial\mathcal{R}_1(0) \). Hence, let \((\tilde{t}, \tilde{z})\) comply with (5.14).

In particular, \( \mathcal{M}_0(\tilde{r}'(s), \tilde{z}'(s), d_2(-D_2\mathcal{I}(\tilde{t}(s), \tilde{z}(s), \partial\mathcal{R}_1(0)))) < \infty \) for a.a. \( s \in (0, S) \), which yields that

\[
\tilde{r}'(s) > 0 \quad \Rightarrow \quad d_2(-D_2\mathcal{I}(\tilde{t}(s), \tilde{z}(s), \partial\mathcal{R}_1(0))) = 0.
\]

(5.17)

Therefore, for \((\tilde{t}, \tilde{z})\) the following inequality holds

\[
\int_0^\sigma \mathcal{M}_0(\tilde{r}'(s), \tilde{z}'(s), d_2(-D_2\mathcal{I}(\tilde{t}(s), \tilde{z}(s), \partial\mathcal{R}_1(0)))) \, ds + \mathcal{I}(\tilde{t}(\sigma), \tilde{z}(\sigma)) \\ \leq \mathcal{I}(\tilde{t}(0), \tilde{z}(0)) + \int_0^\sigma \partial_s \mathcal{I}(\tilde{t}(s), \tilde{z}(s)) \tilde{r}'(s) \, ds \\ = \int_0^\sigma \mathcal{M}_0(\tilde{r}'(s), \tilde{z}'(s), d_2(-D_2\mathcal{I}(\tilde{t}(s), \tilde{z}(s), \partial\mathcal{R}_1(0)))) \, ds + \mathcal{I}(\tilde{t}(\sigma), \tilde{z}(\sigma))
\]

for all \( \sigma \in [0, S] \). Then, with the very same arguments as in the proof of Proposition 3.2, we find that \((\tilde{t}, \tilde{z})\) complies with (5.9) for all \( 0 \leq \sigma_1 \leq \sigma_2 \leq S \).
Proof of Theorem 5.3. From estimate (5.4), we deduce that there exists \( (\hat{t}, \hat{z}) \in C_{lip}([0, S]; [0, T] \times \mathcal{Z}) \) such that convergences (5.11) hold along some subsequence. Arguing as in the proof of Theorem 4.3 and relying on Corollary 2.9, we then find that, for all \( s \in [0, S] \)

\[
\liminf_{n \to \infty} \mathcal{I}(\hat{u}_n(s), \hat{z}_n(s)) \geq \mathcal{I}(\hat{t}(s), \hat{z}(s)), \quad D_2 \mathcal{I}(\hat{u}_n(s), \hat{z}_n(s)) \to D_2 \mathcal{I}(\hat{t}(s), \hat{z}(s)) \text{ weakly in } \mathcal{Z}^*,
\]

\[
\partial_t \mathcal{I}(\hat{u}_n(s), \hat{z}_n(s)) \to \partial_t \mathcal{I}(\hat{t}(s), \hat{z}(s)) \quad \text{in } L^p(0, S) \text{ for all } 1 \leq p < \infty.
\] (5.19)

Now, (5.12) follows by taking the limit as \( \epsilon_n \to 0 \) in (5.4), with a trivial lower semicontinuity argument. Thanks to Lemma 5.1 and convergences (5.19), we have that, for all \( 0 \leq \sigma \leq S \)

\[
\liminf_{\epsilon_n \to 0} \int_0^\sigma \mathcal{M}_\epsilon(\hat{t}_\epsilon'(s), \hat{z}_\epsilon'(s), d_2(-D_2 \mathcal{I}(\hat{u}_\epsilon(s), \hat{z}_\epsilon(s)), \partial \mathcal{R}_1(0))) \, ds 
\geq \int_0^\sigma \mathcal{M}_0(\hat{t}'(s), \hat{z}'(s), d_2(-D_2 \mathcal{I}(\hat{t}(s), \hat{z}(s)), \partial \mathcal{R}_1(0))) \, ds.
\]

Then, combining (5.11) and (5.19), and using that \( \hat{z}_\epsilon(0) = z_\epsilon(0) = z_0 \) for all \( \epsilon > 0 \), we pass to the limit in (5.6) written for \( \sigma_1 = 0 \) and \( \sigma_2 = \sigma \). We thus find that the pair \( (\hat{t}, \hat{z}) \) satisfies (5.14) for all \( 0 \leq \sigma \leq S \).

In view of Lemma 5.6, we conclude that \( (\hat{t}, \hat{z}) \) is a parameterized solution. \( \square \)

5.2 Properties of non-degenerate parameterized solutions

The following characterization of non-degenerate parameterized solutions was proved in [MRS12a, Prop. 5.3, Cor. 5.4]. Adapted to our setting, it reads

Proposition 5.7 (Differential characterization). Let \( s = d/2 \). Assume (2.1), (2.8)–(2.10), and (2.16). Then, a pair \( (\hat{t}, \hat{z}) \in C_{lip}([0, S]; [0, T] \times \mathcal{Z}) \) is a non-degenerate \( \mathcal{Z} \)-parameterized solution of (1.6), if and only if there exists a Borel function \( \lambda : (0, S) \to [0, +\infty) \) such that

\[
\begin{cases}
\partial \mathcal{R}_1(\hat{z}'(s)) + \lambda(s)\hat{z}'(s) + D_2 \mathcal{I}(\hat{t}(s), \hat{z}(s)) \geq 0, \\
\hat{P}(s)\lambda(s) = 0
\end{cases}
\]

for a.a. \( s \in (0, S) \). (5.20)

Remark 5.8 (Mechanical interpretation). As in [MRS12a, Rmk. 5.6] (see also [EM06, MRS09]), from the differential characterization (5.20) of parameterized solutions we may draw the following conclusions on the evolution described by the notion of parameterized solution:

- the regime \( (\hat{t}' > 0, \hat{z}' = 0) \) corresponds to sticking;
- the regime \( (\hat{t}' > 0, \hat{z}' \neq 0) \) corresponds to rate-independent evolution: From the second of (5.20) and \( \hat{P}(s) > 0 \) we deduce that \( \lambda(s) = 0 \), hence the first of (5.20) reads

\[
\partial \mathcal{R}_1(\hat{z}'(s)) + D_2 \mathcal{I}(\hat{t}(s), \hat{z}(s)) \geq 0
\]

where only the rate-independent dissipation is present;
- when \( (\hat{t}' = 0, \hat{z}' \neq 0) \) (note that the latter condition is implied by the non-degeneracy (5.10)), the system has switched to a viscous regime. The latter is seen as a jump in the (slow) external time scale, encoded by the time function \( \hat{t} \), which is frozen. Since \( \hat{P}'(s) = 0 \), the second of (5.20) is satisfied and \( \lambda(s) \) may be strictly positive. In this case, in the first of (5.20) also viscous dissipation is active. Indeed, (5.20) describes the energetic behavior of the system at jump points, see also [MRS09, MRS12a].
5.3 Alternative reparameterization techniques and conclusions

As we have already mentioned in the introduction, in the papers [MRS09, MRS12a] and [EM06, Mie11, MZ12], the vanishing viscosity analysis of rate-independent systems has been developed by reparameterization techniques as well, however based on choices of the parameterization functions different from our own (5.2).

The reparameterization considered in [MRS09, MRS12a] (see also the forthcoming [MRS12c]) would feature, in the present setting, the “energetic quantity”

\[ \tilde{s}_\varepsilon(t) = \int_0^t (1 + \mathcal{R}_\varepsilon(z'_\varepsilon(\tau)) + \mathcal{R}_\varepsilon^*(D\mathcal{I}(\tau, z_\varepsilon(\tau)))) \, d\tau \]  

which can be considered as some sort of energy-dissipation arclength of the viscous solution \( z_\varepsilon \). In fact, under the sole assumption \( z_0 \in Z \), from the energy identity (3.7) fulfilled by viscous solutions it is immediate to deduce that \( sup_{t>0} \tilde{s}_\varepsilon(T) < +\infty \).

On the other hand, the \( L^1(0, T; \mathbb{Z}) \)-estimate (5.1) for \( z'_\varepsilon \) (which can be proved under the additional condition \( D_z\mathcal{I}(0, z_0) \in L^2(\Omega) \)) clearly yields that \( sup_0 \int_0^T \| z'_\varepsilon(\tau) \|_{L^2(\Omega)} \, d\tau \leq C < \infty \). In principle, this would also allow us to reparameterize by the \( L^2(\Omega) \)-arclength

\[ \tilde{s}_\varepsilon(t) = \int_0^t (1 + \| z'_\varepsilon(\tau) \|_{L^2(\Omega)}) \, d\tau \]  

of the graph of \( z_\varepsilon \), like in [Mie11, MZ12]. The advantage of the \( L^2 \)-arclength reparameterization, in comparison with the energy-dissipation arclength and the \( Z \)-arclength reparameterizations, is that it leads to a more understandable “parameterized formulation”, both on the \( \varepsilon \)-level and in the vanishing viscosity limit. More precisely, setting \( \tilde{\ell}_\varepsilon(s) := \tilde{s}_\varepsilon^{-1}(s) \), \( \tilde{z}_\varepsilon(s) := z_\varepsilon(\tilde{\ell}_\varepsilon(s)) \) for \( s \in [0, \tilde{s}_\varepsilon(T)] \), it can be easily calculated that the pair \((\tilde{\ell}_\varepsilon, \tilde{z}_\varepsilon)\) fulfills

\[
\begin{cases}
\tilde{\ell}_\varepsilon(0) = 0, \quad \tilde{z}_\varepsilon(0) = z_0, \\
\tilde{\ell}_\varepsilon(s) + \| \tilde{z}_\varepsilon'(s) \|_{L^2(\Omega)} = 1, \\
\partial \mathcal{R}_1(\tilde{z}_\varepsilon'(s)) + \frac{\varepsilon}{1 + \| \tilde{z}_\varepsilon'(s) \|_{L^2(\Omega)}} \tilde{z}_\varepsilon'(s) + D_z\mathcal{I}(\tilde{\ell}_\varepsilon(s), \tilde{z}_\varepsilon(s)) \geq 0
\end{cases}
\text{for a.a.s } s \in (0, \tilde{s}_\varepsilon(T)).
\]  

(5.23)

As in [Mie11, Section 4.4] (cf. also [EM06, MZ12]), one observes that the \( \varepsilon \)-viscous term is the subdifferential of the potential \( \mathcal{V}_\varepsilon \), which is defined for every \( \eta \in L^2(\Omega) \) as follows:

\[ \mathcal{V}_\varepsilon(\eta) = \varepsilon v \left( \| \eta \|_{L^2(\Omega)} \right) \quad \text{with } v(\xi) = \begin{cases} -\log(1 - \xi) - \xi & \text{if } \xi < 1, \\ +\infty & \text{else}. \end{cases} \]

With \( \tilde{\mathcal{R}}_\varepsilon(\eta) := \mathcal{R}_1(\eta) + \mathcal{V}_\varepsilon(\eta) \), the differential inclusion in (5.23) can be rewritten as

\[ \partial \tilde{\mathcal{R}}_\varepsilon(\tilde{z}_\varepsilon'(s)) + D_z\mathcal{I}(\tilde{\ell}_\varepsilon(s), \tilde{z}_\varepsilon(s)) \ni 0 \text{ for a.a.s } s \in (0, \tilde{s}_\varepsilon(T)). \]  

(5.24)

Notice that (5.24) has the same structure as the “viscous” doubly nonlinear equation (3.1). It can be checked (cf. with [MZ12, Lemma A.4] in the reversible case \( \mathcal{R}_1(\cdot) = \| \cdot \|_{L^2(\Omega)} \)), that the potential \( \tilde{\mathcal{R}}_\varepsilon \) converges monotonously to the limit functional \( \tilde{\mathcal{R}}_0 \) with \( \tilde{\mathcal{R}}_0(\eta) = \mathcal{R}_1(\eta) \) if \( \| \eta \|_{L^2(\Omega)} \leq 1 \) and \(+\infty\) else.

Therefore, recalling the results in [Mie11, MZ12], it is to be expected that, up to a subsequence, the pairs \((\tilde{\ell}_\varepsilon, \tilde{z}_\varepsilon)\) converge to \((\tilde{\ell}, \tilde{z}) \in C^0_{\text{lip}}([0, \tilde{S}] ; [0, T] \times L^2(\Omega)) \) (with \( \tilde{S} = \lim_{\varepsilon \to 0} \tilde{s}_\varepsilon(T) \)), satisfying

\[
\begin{cases}
\tilde{\ell}(0) = 0, \quad \tilde{\ell}(T) = T, \\
\tilde{\ell}'(s) \geq 0, \quad \tilde{\ell}'(s) + \| \tilde{z}'(s) \|_{L^2(\Omega)} \leq 1, \\
\partial \tilde{\mathcal{R}}_0(\tilde{z}'(s)) + D_z\mathcal{I}(\tilde{\ell}(s), \tilde{z}(s)) \ni 0
\end{cases}
\text{for a.a.s } s \in (0, \tilde{S}).
\]  

(5.25)
However, at the moment we are not able to prove this convergence result. Our main difficulty in the passage to the limit as $\epsilon \searrow 0$ in (5.24) is related to the unboundedness of the operator $\partial R_1$. Because of this, it is not possible to perform those comparison estimates in (5.24), which would give a bound in $L^2(0, \tilde{S}; L^2(\Omega))$ for the term $D_z I(\tilde{t}(\cdot), \tilde{z}(\cdot))$. As it stands, such a term is only estimated in $L^\infty(0, T; Z^*)$, which is not sufficient for passing from (5.24) to (5.25), since we only have an $L^1(0, T; L^2(\Omega))$-bound for $(\tilde{z}'_\epsilon)$. Roughly speaking, the terms $D_z I(\tilde{t}, \tilde{z})$ and $\tilde{z}'_\epsilon$ are no longer “in duality”: This prevents us from applying the passage to the limit techniques developed in [MZ12] for the “reversible” case. Furthermore, we cannot develop the “energetic” arguments of the proof of Theorem 5.3 any longer. Indeed, in this new setting it would still be possible to prove that $(\tilde{t}, \tilde{z}_{\epsilon})$ converge in suitable topologies to a pair $(\tilde{t}, \tilde{z}) \in C^0_{\text{lip}}([0, \tilde{S}]; [0, T] \times L^2(\Omega))$ which satisfies the energy inequality related to the limit problem (5.25):

$$I(T, \tilde{z}(S)) + \int_0^S \tilde{R}_0(\tilde{z}'(s)) \, ds + \int_0^S (\tilde{R}_0)^* \left( -D_z I(\tilde{t}(s), \tilde{z}(s)) \right) \, ds$$

$\leq I(0, \tilde{z}(0)) + \int_0^S \partial_t I(\tilde{t}(s), \tilde{z}(s)) \tilde{t}'(s) \, ds$.  \hfill (5.26)

Still, from (5.26) we would not be able to conclude that (5.25) holds via chain rule arguments, like in the proof of Theorem 5.3. In fact, we do not dispose of the “parameterized chain rule” (5.15) any longer, due to the lack of further spatial regularity for $D_z I(\tilde{t}, \tilde{z})$.

The vanishing viscosity analysis via the energy-dissipation arclength reparameterization would bring forth the same difficulties. Nonetheless, we plan to address these issues in the future, relying on some improved regularity results for the term $D_z I(t, z_\epsilon(t))$ in (3.1).
